From: Commanding Officer, U. S. Fleet Weather Central/Joint Typhoon
Warning Center, Guam
To: Chief of Naval Operations
Via: Commander in Chief, U. S. Pacific Fleet

Subj: Annual Typhoon Report, 1967; submission of

Ref: (a) OPNAV Instruction 3140.17E of 29 Oct 65
(b) SECNAV Instruction 5600.16 of 2 Nov 60

1. The Annual Typhoon Report, 1967, is submitted herewith in accordance with reference (a).
2. During calendar year 1967, a total of 20 typhoons, 15 tropical storms and six tropical depressions were detected in the Western North Pacific area between 180 degrees longitude and the Malay Peninsula, north of the equator, for which 957 warnings were issued. FWC/JTWC, Guam was in a "Warning Status" for 185 calendar days. Both the number of warnings issued and the number of days in warning were records over any previous year. 1967 was an unusual year in that tropical cyclone development occurred farther north than normal when compared with previous years. Also, cyclone tracks were noticeably scattered and erratic during the 1967 season as they were in 1966.
3. Reference (a) directed the Fleet Weather Centrals at Pearl Harbor and Alameda to forward summaries of tropical cyclones in their areas to the Fleet Weather Central/Joint Typhoon Warning Center, Guam, for inclusion in the subject report. Fleet Weather Central Alameda issued a total of 422 warnings on five hurricanes, 12 tropical storms and two tropical depressions in their area of responsibility. Fleet Weather Central Pearl Harbor issued a total of 52 warnings on one hurricane and two tropical storms. A summary of tropical cyclones east of 180 degrees longitude is included in Annex A. Position data for tropical cyclones one through eight in Fleet Weather Central Alameda area of responsibility were not available at the time of publication.
4. This report has been reviewed in accordance with reference (b).

J. H. NEGELE

FOREWORD

This report is published annually and summarizes Western North Pacific Tropical Cyclones. Annex A is added to summarize Tropical Cyclones from 180 degrees eastward to the North American Coast.

When directed by CINCPAC in May 1959, CINCPACFLT redesignated Fleet Weather Central Guam as Fleet Weather Central/Joint Typhoon Warning Center (FWC/JTWC), Guam with the following responsibilities:

1. To provide warnings to U. S. Government agencies for all tropical cyclones west of 180 degrees longitude north of the equator to the Asiatic coast and Malayan Peninsula.
2. To determine tropical cyclone reconnaissance requirements and assign priorities.
3. To conduct investigative and post analysis programs including preparation of the Annual Typhoon Report.
4. To conduct tropical cyclone forecasting and detection research as practicable.

Fuchu Air Force Weather Central, coordinating with Fleet Weather Facility Yokosuka was designated as alternate JTWC in case of failure of FWC/JTWC Guam.

The JTWC, which is an integral section of FWC/JTWC Guam, is staffed by three Air Force and three Navy meteorologists and three enlisted men from each service. The senior Air Force Officer has been designated as the Director, JTWC.

The Joint Hurricane Warning Center in Hawaii, a coordinated agency composed of the U. S. Weather Bureau, Honolulu, the Air Force Kunia Weather Center, and Fleet Weather Central Pearl Harbor, is responsible for surveillance and issuance of warnings in the Central North Pacific area north of the equator between 180 degrees and 140 degrees west.

The Fleet Weather Central, Alameda, California, is responsible for issuance of warnings between 140 degrees west and the North American Coast.

A. GENERAL

Operational procedures involve the sequence of events leading to the issuance of tropical cyclone warnings, the chief product of the Joint Typhoon Warning Center (JTWC). This includes analysis of all available data, use of forecast aids to arrive at the forecast track, and preparation and transmission of the warnings. Within the Fleet Weather Central/Joint Typhoon Warning Center (FWC/JTWC), collection and basic analysis of data is the responsibility of the FWC. This includes receipt of analyses and prognosis from Fleet Numerical Weather Facility (FNWF), Monterey through the Naval Environmental Data Network (NEDN). JTWC is responsible for meso-scale analyses, collection of reconnaissance data, making tropical cyclone forecasts, and preparation of warning bulletins. Transmission of the warnings is accomplished by the communications section of FWC, operated by the Naval Communications Station, Guam.

B. ANALYSES AND DATA SOURCES

1. FWC Analyses:

- a. Surface isobaric; 0000Z, 0600Z, 1200Z, and 1800Z.
- b. Surface isobaric, micro-analyses of South China Sea; 0000Z and 1200Z.
- c. Gradient level streamlines; 0000Z, 0600Z, 1200Z and 1800Z.
- d. 850 mb streamlines; 0000Z and 1200Z.
- e. 700 mb streamlines; 0000Z and 1200Z.
- f. 500 mb streamlines; 0000Z and 1200Z.
- g. 200 mb streamlines; 0000Z and 1200Z.
- h. Sea Surface Temperature Charts; 5-day mean and daily.
- i. Checkerboards (Stidd diagrams) of selected tropical stations.
- j. Time cross sections of selected tropical stations.
- k. Selected upper air soundings.
- l. AROWAGRAM for Guam.
- m. Nephanalyses.

2. JTWC Analyses:

- a. Sectional surface charts; hourly and 3-hourly, as required.
- b. Reconnaissance data.
- c. 700 mb meso-scale contours; 0000Z and 1200Z.
- d. 500 mb meso-scale contours; 0000Z and 1200Z.
- e. 300 mb meso-scale contours; 0000Z and 1200Z.
- f. Stidd diagram for selected stations as required when special observations are requested.
- g. 500 mb contour; Western North Pacific; 0000Z and 1200Z.

3. Satellite Data:

JTWC received excellent cloud picture coverage throughout 1967 from the ESSA II and NIMBUS satellites through the APT receiver at FWC. Gridding and display procedures have greatly improved, making these satellite cloud pictures of high value in determining formation, size, and location of tropical cyclones. The daily passes of the APT satellites received at Guam normally cover the majority of the JTWC area. In order to extend the area of coverage, an experimental exchange of satellite pictures between FWC Pearl Harbor, FWC Guam, and FWF Sangley Point over the NEDN transmission lines was begun this year. While quality has been erratic to date, the system has been useful and shows good future possibilities.

The satellite bulletins issued by the National Environmental Satellite Center (NESC) and the gridded cloud picture mosaics also originated by NESC have both been very useful. The latter cover the entire tropical Pacific Ocean and have been transmitted experimentally through the ATS satellite.

4. Land Radar:

Land radar reports are very helpful when tropical circulations are approaching or are over land areas. These reports include range and bearing of the eye from the radar station, eye characteristics, and sometimes the direction and speed of movement of the center.

5. Computer Products from FNWF, 0000Z and 1200Z:

a. Hemispheric analyses and barotropic prognoses (out to 72 hours) for surface (isobaric); 850mb, 700mb, 500mb, 300mb, and 200mb levels (contours); and 700mb, 500mb, and 300mb levels (isotachs).

b. Computer hemispheric contour analyses of 700mb, 500mb and 300mb levels are locally expanded onto large polar projection charts for the Western North Pacific area.

c. Computer analyses and prognoses of wind fields in printed format at 5 degree intervals of longitude and 1 degree intervals of latitude for 700mb and 500mb levels; Western North Pacific.

d. FNWF 500mb decomposition fields, SD, SR, and SL analyses and prognoses which correspond roughly to small scale disturbances, mean flow, and long wave pattern, respectively.

C. FORECAST AIDS

1. Climatology:

The following climatological publications were utilized:

- a. Tropical Cyclones in the Western Pacific and China Sea Area (Royal Observatory, Hong Kong), covering 70 years of typhoon tracks.
- b. Climatological Aid to Forecasting Typhoon Movement (1st Weather Wing).
- c. Climatological 24-hour typhoon movement (McCabe, J. T., 1961).
- d. Western Pacific Typhoon Tracks, 1950-1959 (FWC/JTWC).
- e. Far East Climatic Atlas (First Weather Wing, February 1963).
- f. Annual Typhoon Report, 1965 (FWC/JTWC), covering tracks for 1953-1965.
- g. Annual Typhoon Report, 1966 (FWC/JTWC), covering tracks for 1965-1966.

2. Persistence:

Extrapolation of tropical cyclone tracks from past positions was always considered along with climatology in making up initial tracks and in making the "first draft", so to speak, of any forecast. Extrapolation has proven to be one of the most reliable techniques for a 12 to 24 forecast period, as shown by the JTWC computer verification program (See Chapter III).

3. Computer Products:

In addition to the computer prognoses detailed in paragraph B.5. above, forecast positions based on steering trajectories at the 1000mb, 700mb, and 500mb levels were available for 6, 12, 18, 24, 36, 48, and 72-hour positions. These steers came from the HATRACK program which is outlined in Chapter III. These forecasts were available from FNWF and were obtained after each fix was received. Toward the end of the 1967 season this computer program was adapted for running on the FWC, Guam computer on a trial basis, thus providing computer steering on a more convenient and timely basis. This should be fully operational for the 1968 typhoon season.

4. Objective Techniques:

During the 1967 typhoon season the following individual objective techniques were used by JTWC:

- a. Arakawa - using surface data.
- b. Tse - using 700mb data.

See Chapter III for verification of these techniques, along with verification of extrapolation, climatology, and computer steering, using the JTWC computer verification program.

D. FORECASTING PROCEDURE

In preparation for issuance of the initial warning on a tropical cyclone, a track based on climatology and extrapolation is developed for a time period of 3 or 4 days. The track is then modified in accordance with the existing and forecast upper air patterns. Numerical steering forecasts and objective techniques are also considered before the initial warning is issued.

Subsequently, the basic track is modified as dictated by consideration of all forecast aids. For each forecast, extrapolation is checked against climatology, objective techniques, and numerical steering forecasts, with extrapolation being favored for a 12 to 24 hour period. Subjective modifications are also based on meso-analyzed 700mb, 500mb and 300mb charts and on numerical hemispheric prognoses. 200 mb streamline analyses provide indications of divergent areas relating to changes in intensity.

The resulting forecast track is thus a subjective integration of these many factors, with extrapolation and numerical steering being most heavily weighted for short period forecasts, while climatology and forecast flow patterns govern the longer range outlooks.

E. WARNINGS

In the JTWC area of responsibility, tropical cyclone warnings are issued at 0000Z plus every six hours. In accordance with CINCPAC INST. 3140.1H, the warning message contains the position of the tropical cyclone which is valid for the scheduled transmission time. Therefore, the 24-hour and 48-hour forecasts are actually 30-hour and 54-hour forecasts from the last available synoptic data.

The warning position of a tropical cyclone is actually a short range forecast from the last "best" position. The last "best" position is usually about 2 hours old based on land radar or reconnaissance fixes, 3 to 6 hours old based on surface synoptic reports, or 6 to 12 hours old based on upper air synoptic reports. It is for this reason that the 0600Z warning, for example, may not agree with the position of the tropical cyclone as indicated by the 0600Z analysis. Amendments are issued when this difference is significant.

The numbering of tropical cyclone warnings runs consecutively regardless of whether the cyclone is upgraded or downgraded from one stage to another. If warnings are discontinued and the circulation regenerates, the new series of warnings are numbered consecutively from the number of the last warning of the previous series. Amendments and corrections which are issued as required are given the same numbers as the warnings which they amend or correct.

When tropical cyclones become extratropical before dissipating, a final warning is issued by JTWC and extratropical warning responsibility is transferred to the appropriate Fleet Weather Central.

All 24, 48, and 72-hour forecasts made when a tropical cyclone is of tropical storm or typhoon intensity are verified against the "best track" as determined by post-analysis. The 1967 verification summary is contained in Chapter IV.

In addition to the tropical cyclone warnings, JTWC issues a prognostic reasoning twice daily for a 72-hour period for tropical storms and typhoons. A tropical weather summary for the JTWC area of responsibility is issued each day at 0600Z from 1 May through 31 December.

CHAPTER II RECONNAISSANCE

A. GENERAL

Land stations in the tropical Pacific are sparse. Although additional observing units have been activated during the past year and more are expected to be located at strategic sites in the future, the stations will continue to remain widely scattered. Ships which transmit weather observations are usually concentrated along the shipping lanes which do not pass through the areas of formation and development of tropical systems. Also, ships which are near a tropical cyclone will normally take evasive action as soon as the first warning is received. The pictures from the ESSA and NIMBUS weather satellites have proven to be a tremendous aid, especially in initial detection of suspect areas. However, satellites cannot report the wind, pressure, and other important meteorological parameters needed to properly analyze a tropical cyclone. Aerial reconnaissance thus remains the only method to provide sufficient surface and upper air data for complete and proper analysis of a tropical cyclone.

Reconnaissance aircraft can remain in the vicinity of a storm to provide an accurate position and to report storm characteristics such as eye shape, intensity, and extent of cloud patterns. By taking dropsondes or making ascent or descent soundings, the aircraft obtains the lapse rate profile to the surface, heights of standard levels, sea level pressures, and temperature and dew point at any level.

The accuracy of tropical warnings is directly related to the quality and quantity of reconnaissance data received from the aircraft. Continuous surveillance of tropical systems is of the utmost importance in order to insure that warnings are issued in time to facilitate proper preparations for safeguarding life and property.

B. RECONNAISSANCE RESPONSIBILITY

During 1967 two squadrons were assigned the responsibility of tropical cyclone reconnaissance to meet the requirements of the Joint Typhoon Warning Center, Guam. These squadrons were the U. S. Navy Airborne Early Warning Squadron One (VW1), equipped with the EC121K aircraft based at the Naval Air Station, Agana, Guam and the U. S. Air Force 54th Weather Reconnaissance Squadron (54WRS), equipped with WC-130 aircraft based at Andersen Air Force Base, Guam.

C. EVALUATION OF DATA

During the 1967 season, four fixes per day were normally scheduled on typhoons and tropical storms. Tropical Depressions were

scheduled for one or more fixes per day depending on location, potential, and feasibility of radar coverage.

In general, low (1500ft or below) or intermediate (700mb) level fixes were made by VW1 at 1000Z and 1600Z, and intermediate level fixes were made by the 54WRS at 2200Z and 0400Z. High level (500mb) fixes were made on storms in the vicinity of high terrain. In addition to the fixes, both squadrons flew synoptic and investigative flights throughout the year.

Aerial reconnaissance can be divided, according to data gathered, into three categories: peripheral data, eye data from penetration, and eye data from radar.

Peripheral data is all information reported enroute to and outside the eye of the storm. It includes hydrometeor description, sea level pressure, pressure-height, a complete description of clouds including types, amount and heights of bases and tops, flight altitude winds, temperature, dew point, and surface winds. This same type of data is provided on all synoptic tracks and investigations.

Eye data from penetration includes all information reported in peripheral data plus eye size, shape, description, slope, cloudiness, maximum flight level wind, maximum temperature inside and outside the eye, and maximum surface wind. Remarks which might be of help to the forecaster such as feeder band description, and direction and speed movement of the center are also included.

Eye data from radar provides a description of the radar eye and its location, including description of spiral bands and height and width of the wall cloud. Also included is the aircraft position at the time the radar observation is taken and the maximum observed winds when available.

On all eye messages a center selection evaluation is made. An evaluation of "Positive", "Fair", or "Poor" is given along with an estimate of the navigational accuracy of the fix and the type of navigation used by the aircraft. These were used by JTWC as a guide in evaluating fix accuracy. When radar fixes are made from a considerable distance, attenuation can distort the radar image; therefore, the distance of the aircraft from the storm center must be considered when evaluating the radar fix.

During 1967, daylight penetrations were made on all but a few of the most severe storms. When possible, EC121K aircraft also penetrated the storms for night fixes. Many of the night penetrations were made at 1500 feet or below, especially when the storms were too weak for radar coverage. Location of the circulation center with the aid of the aircraft landing lights was not uncommon when the center could not be determined by other means.

AIRCRAFT RECONNAISSANCE DATA
(Number of Fixes and Investigations)

1961	1962	1963	1964	1965	1966	1967
350	496	465	772	666	674	845*

* 112 No Credit (see Paragraph E) not included.

112
957

In addition there were 484 synoptic tracks flown by the two squadrons during 1967.

The information from the aircraft was continually checked for consistency and accuracy. Where possible, JTWC graphs and other aids were used to check and compare data with previous reports. Verification was immediately requested from the observing aircraft on any apparent discrepancy in the data.

D. COMMUNICATIONS

The primary means of communications between ground stations and reconnaissance aircraft was voice single sideband. Andersen Airways (AIE2), Guam was the primary air to ground station for 54WRS aircraft. The Joint Typhoon Warning Center "Enjoyment" circuit was the primary air to ground station for VW1 aircraft for relay of weather messages. Clark Airways (AIC2), Republic of the Philippines, Fuchu Airways (AIF2), Japan, and Kadena Airways (AID2), Okinawa, were the secondary air to ground stations. Data received by AIE2 were relayed to JTWC by local teletype circuit SDE 9. This circuit also connects VW1, 54WRS, NCS Guam, and Naval Air Station, Agana, Guam. Data received by AIC2, AIF2, and AID2 were relayed to JTWC through the Defense Communications System.

When aircraft were in contact with AIE2 or JTWC "Enjoyment" circuit, reports were normally received by JTWC in sufficient time to allow the forecaster to make a comprehensive study of the information prior to warning time. The extensive use of these two means of communications made it operationally feasible for JTWC to adjust the fix times to two hours prior to warning time vice three hours as in previous years. This provided more current and timely data for the issuance of warnings. However, when the aircraft had to communicate through one of the secondary stations there were many cases of excessive delay in receipt of the eye data. In some instances it was not received until after warning time.

A comparison of the JTWC "Enjoyment" circuit delay times with the next most reliable means, Andersen Airways via the SDE 9 circuit, revealed an average delay time difference of 23 minutes in favor of "Enjoyment".

The average delay time from the aircraft to JTWC direct was 30 minutes. This includes the delay in the aircraft by the meteorologist, and the time for JTWC to copy the complete eye data message. The maximum delay over the JTWC circuit was 3 hours, 41 minutes and the minimum delay just a few minutes. Receipt of the eye data message in less than 10 minutes from fix time was not uncommon when the flight meteorologist expedited the message and communications were good. One of the more noticeable advantages of "Enjoyment" was the elimination of excessive delay in receiving data from remote areas such as the South China Sea. NCS Guam, by using high gain antennas especially suited for receipt of data from particular geographical areas, was able to provide communications with the aircraft even under adverse conditions. Another distinct advantage of direct communications with the aircraft was the ability to clarify doubtful data with minimal delay. Also, relay of the latest meteorological data directly to the flight meteorologist on investigative flights often provided more useful information and permitted the aircraft to remain in the area longer for a thorough investigation, since late information such as satellite readout gave a more exact location of the suspect area.

The constant use of the "Enjoyment" circuit required an excessive number of man hours by JTWC personnel in direct communications with the aircraft and subsequent relay of the weather reconnaissance data through the Defense Communications System. The limited number of personnel assigned to JTWC and the lack of qualified communications personnel precludes the continued use of this system.

A method to improve existing communications and also preclude the need for additional personnel to work the "Enjoyment" circuit was requested by JTWC to CINCPAC. If approved, the 54WRS weather monitor would be tasked with the processing and retransmission of all RAINPROOF VWL weather reconnaissance observations. In addition, discrete frequencies would be assigned for the relay of weather reconnaissance observations to preclude preemption by other airways traffic.

The addition of a telephone line from Andersen Airways to JTWC with the associated monitoring equipment has been approved. This will enable JTWC to monitor incoming weather reconnaissance data simultaneously with the receipt by the 54WRS weather monitor and provide direct phone patch capability with the reconnaissance aircraft when required.

The following statistics show the delays between time of fix and time of first receipt at JTWC. The methods used in getting the fix to JTWC are shown for comparison.

DELAY IN RECEIPT OF RECONNAISSANCE FIX DATA FOR 1967

METHOD	NUMBER OF CASES	MAX DELAY TIME	MIN DELAY TIME	AVG DELAY TIME
SDE9	346	2 HR 44 MIN	0 HR 18 MIN	0 HR 52 MIN
ENJOYMENT	460	3 HR 41 MIN	0 HR 04 MIN	0 HR 30 MIN
OTHER	70	11 HR 20 MIN	0 HR 05 MIN	1 HR 24 MIN

Table II-1 contains some revealing statistics on communications delays encountered in 1967 along with figures from previous years for comparison.

A COMPARISON OF DELAY TIME WITH PREVIOUS YEARS

	1964	1965	1966	1967
MAX DELAY TIME	60 HRS 45 MIN	60 HRS 09 MIN	4 HRS 33 MIN	11 HRS 20 MIN
AVG DELAY TIME	1 HR 14 MIN	1 HR 05 MIN	1 HR 02 MIN	0 HR 43 MIN
MIN DELAY TIME	8 Minutes	9 Minutes	"Few Minutes"	"Few Minutes"
% OF EYE MESSAGES DELAYED MORE THAN 1 HOUR	59%	39%	38%	16%

TABLE II-1

E. SUMMARY OF RECONNAISSANCE SUPPORT

In an effort to make the crediting of the reconnaissance effort more objective and meaningful, a system was devised in 1965 to credit fixes and investigations. The same system, with minor changes, was used during the 1966 and 1967 seasons. First of all, the problems of why a fix was early, late or missed completely, although of interest and concern to JTWC, belong to the Tropical Cyclone Reconnaissance Coordinator (TCRC). The time of warning and inherent delay from scheduled fix times were the determining factors used in the crediting scheme. Obviously, it would be desirable to have the fix made as near warning time as possible, and in the past it was necessary to have the fix times scheduled 3 hours prior to warning time because of communications delays. However, more rapid communications during 1967 permitted JTWC to adjust these fix times to 2 hours prior to warning time. This usually allowed ample time to digest the information after receipt of the data. The crediting system is described below.

DEFINITIONS OF FIX CREDITS

<u>CLASS</u>	<u>DEFINITION</u>	<u>FIX CRITERIA</u>
1	Full Credit	From 1 hour before to $\frac{1}{2}$ hour after levied time.
2	Full Credit	Aircraft in area requested within 1 hour before to $\frac{1}{2}$ hour after levied time but unable to locate a center.
3	Early/Late	Center located 1 to $1\frac{1}{2}$ hours before or $\frac{1}{2}$ to 2 hours after levied time.
4	Very Early/Very Late	Greater than $1\frac{1}{2}$ hours before or more than 2 hours after levied time.
5	Attempted but missed fix	Recon provided some useful peripheral data but no fix was made. Reasons may include clearance problems, mechanical trouble, low fuel, etc.
6	Missed Fix	Missed fixes not falling into any category above.
7	Full Credit	Fix made on investigative flight or synoptic track.
8	Full Credit	Investigative flight, no fix made.
9	No Credit	Preliminary or intermediate fix made between scheduled fixes.

This system, although as objective as possible, requires subjective evaluation of some fixes. For example, an aircraft could be in the area assigned on time, but unexpected storm acceleration could make the cyclone too distant to be reached within normal fix time limits. In this case, full credit is given with no penalty for being late.

Applying the above system for the 1967 season, the following statistics are obtained:

EVALUATION OF TIMELINESS OF RECONNAISSANCE FOR 1967

<u>Class</u>	<u>Number</u>

This Chapter is a collection of studies conducted during the 1967 typhoon season. Some topics appear in their entirety. Other topics are of a continuing nature and will be completed when data becomes available.

The following is a list of the topics discussed in this Chapter:

- A. A COMPARISON OF OBJECTIVE TECHNIQUES FOR TYPHOON MOVEMENT.
- B. A NOTE ON THE STAGE C - "COMMA CONFIGURATION."
- C. FORECASTING DEVELOPMENT OF TROPICAL CYCLONES.
- D. AN EXAMPLE OF TWO VORTICES WITHIN A LARGE TROPICAL SYSTEM.
- E. PRELIMINARY RESULTS OF USING RECONNAISSANCE PERIPHERAL HEIGHT DATA TO FORECAST TYPHOON MOVEMENT.

A. A COMPARISON OF OBJECTIVE TECHNIQUES FOR TYPHOON MOVEMENT

1. Introduction

Few statistics have been compiled concerning the merits of various forecast methods under operational conditions for tropical cyclones in the Pacific. If a number of forecasts are prepared at a given synoptic time using different methods, the Typhoon Duty Officer (TDO) is confronted with a wide divergence of forecast tracks. Unless it is known which technique is superior in a given situation, little or no weight can be given to any of the objective systems. With this in mind, a study was undertaken to evaluate a large number of objective forecasting techniques for tropical cyclones under operational conditions using numerical methods.

Two sets of logs were maintained on all storms. These logs were prepared to facilitate using numbered codes for all entries. The Best Track log was completed following each tropical cyclone, figure III-1A. The Best Track of a cyclone is a post-analysis summary giving cyclone locations, intensities, and directions and speeds of movement. As the various forecasts were made, the 24 Hour Objective Forecast log was filled out by the TDO, figure III-1B. The logs were double checked for accuracy and the data were cut on Hollerith machine cards. The data card information was read into the computer, processed and printed using the online printer.

A simplified flow diagram of the verification program is depicted in figure III-2. The program is such that one or multiple storms may be run at any one time. Examples of the two printouts produced by the program are shown in figure III-3. The first printout, figure III-3A, gives a summary for each individual tropical cyclone. For each individual technique the following information is listed: the verification time, the vector error from the Best Track position to the forecast position, and the average 24 hour forecast error. The second printout, figure III-3B, provides a summary for all the cyclones plus a stratification of the storms by intensity.

To enable a direct comparison of the various objective techniques with the official forecast under operational conditions, the following procedures were incorporated. The verification times were chosen as 0600Z and 1800Z to facilitate using the latest 0000Z and 1200Z upper air charts. Therefore, in terms of upper air charts, a 24 hour forecast is actually a 30 hour forecast. Reconnaissance fixes are normally taken two hours prior to warning time (0400Z, 1000Z, 1600Z and 2200Z). After receipt of the fix at JTWC, this fix position is extrapolated out for a period of two hours. The extrapolated position is then used on the 0000Z, 0600Z, 1200Z and 1800Z warnings. This extrapolated position was

also used as a base for the various objective techniques. Therefore, in terms of reconnaissance fixes, a 24 hour forecast is in reality a 26 hour forecast--two hour extrapolation plus the 24 hour objective forecast. All intensities of tropical cyclones were verified (tropical depressions, tropical storms and typhoons).

2. Discussion of Forecast Techniques Tested

A brief summary of the forecasting techniques tested follows and are not listed in order of performance.

a. JTWC - The official Joint Typhoon Warning Central, Guam, forecast. It was used for comparison purposes only.

b. Tse [1] - A method which incorporates the 700 mb synoptic pattern into the forecast scheme. The differences in the 700 mb contour height north-south and east-west are used as the predictors. A nomogram is then entered to give the 24 hour forecast position.

c. Arakawa [2] - The Arakawa technique uses regression equations to forecast 24 and 48 hour movement plus intensities. Using a grid overlay, pressures on the latest surface chart are transferred to a worksheet. Simple computations result in the forecast positions.

d. Climatology - The assumption made using this procedure is that a given storm will move the mean direction and speed of all typhoons that have been located at approximately the same latitude and longitude during that month of previous years. Climatological charts used in this study were compiled by Chin [3] .

e. Extrapolation - Extrapolation is a semi-objective method by which the forecast track is determined using past values of speed, direction and intensity.

f. Monterey 500 mb HAT - Numerical steers obtained from Fleet Numerical Weather Facility (FNWF), Monterey, California, over the computer data line. The program, called HAT, was written by FNWF personnel and uses a grid surrounding the tropical cyclone. The 500 mb barotropic height prognosis is heavily smoothed in the area surrounding the storm. The cyclone is treated as a point vortex and is advected in one hour time steps up to a forecast period of 72 hours.

g. Monterey 1000 mb P - Numerical steers obtained from a program called HATRACK. The program was written by Lcdr. B. L. Bradford and Lt. G. A. Brearton at FNWF and is still considered to be experimental in nature. There are two versions of the program, the first using SR prognostic fields and the second using SR analyses fields. SR fields [4] are constant level data

fields in which the small scale disturbances are smoothed out. The storm is advected as a point vortex on the SR field in six hour time steps up to a forecast period of 72 hours. The output steer message gives the following information: (1) name and/or number of the tropical cyclone, (2) date time group of the analysis or forecast field used, (3) time and position of initial request and (4) time, position, and movement vector for each six hour forecast period. A sample output message is shown in figure III-4. Steers were provided at the 1000, 700 and 500 mb levels, however, the program can be modified to use any standard level up to and including 100 mb. The Monterey 1000 mb P technique provides steers using 1000 mb prognostic SR fields.

h. Monterey 700 mb P - Numerical steers using 700 mb prognostic SR fields.

i. Monterey 700 mb A - Same as item "h" except analyses fields are used for the steers.

j. Monterey 700 mb P Modified - A modification of the Monterey 700 mb P technique using history errors. A detailed description of how history errors were applied is contained in part 3.

k. Monterey 500 mb P - Numerical steers using 500 mb prognostic SR fields.

l. Monterey 500 mb A - Same as item "k" except analyses fields are used for the steers.

m. Monterey 500 mb P Modified - A technique similar to item "j" except 500 mb prognostic SR fields are utilized in the steers.

n. Monterey 700 mb A Modified - A method similar to item "j" except analyses rather than prognostic SR fields are used. This technique was used operationally near the end of the typhoon season because of its timeliness. The prognostic SR steers, although resulting in superior forecasts, were often not available until after the tropical cyclone warnings were issued.

3. Description of the Monterey SR Modified Technique

In the pursuit of developing a technique for the improvement of the SR forecasts, a method developed by Hardie [5] was tested and with slight modifications was used. In using a history modification, the assumption is made that forecast errors made in the past will continue to occur in the future. The use of a history modification technique is justified in that it corrects for use of the wrong steering level, use of geostrophic rather than actual wind, and errors that have occurred in the prognostic and analyses fields. A vector diagram depicting the modification tech-

nique is shown in figure III-5.

4. Testing and Results

The procedures outlined in the previous sections were incorporated to predict the 24 hour movement of the 1967 tropical cyclones in the JTWC area of responsibility. The figures in the tables give average forecast errors in nautical miles and the number of cases used to compute the averages in parenthesis. Direct comparisons between the various forecasting techniques are difficult as the sample size was not homogeneous and the life cycle of the storms tested was not always the same. However, all statistics and comparison figures were made using the same cyclones in the sample. When a specific technique was not doing well in comparison with others, a different technique was substituted in its place, therefore, sample sizes vary considerably. Official forecast verification figures are included in all tables for comparison purposes.

Table III-1A depicts three objective techniques--Tse, Arakawa, and Climatology. The Tse technique, although forecasting direction of movement fairly well, appeared to be consistently slow in speed of movement. The Arakawa forecasts did exceptionally well when the atmosphere was vertically consistent up to 500 mb, however, in cases where vertical consistency did not exist, large forecast errors occurred. Although Climatological forecast errors were larger than any other technique, it still proved to be very useful in the lower latitudes where, frequently, insufficient data was available to use the other techniques to advantage.

Evaluation of the Monterey 500 mb HAT Steers, table III-1B, were discontinued early in the season after ascertaining that the new Monterey HATRACK steers were doing much better in comparison.

Extrapolation, as shown by table III-1C, proved to be one of the best short range forecasting techniques available. However, being a semi-objective method, a direct correlation exists between forecast errors and forecaster experience. In addition, in the Pacific region, upper air measurements are sparse and in many cases non-existent regardless of the geographical location of the tropical cyclone. Therefore, in most cases, "educated" extrapolation will result in superior verifications when compared with other techniques that require accurate upper air analyses.

As was previously mentioned in section 2, in most cases the Monterey SR prognostic steers were not available until after the 06Z and 18Z warnings were issued. The prognostic steers were available for use in issuing the 00Z and 12Z warning, however, verification figures were not made at those times. Verification results of the Monterey prognostic steers, given in table III-1D, indicate that overall, the 700 mb level was the best single steering level by a considerable amount.

A comparison of Monterey steers using analyses versus prognostic fields is shown in table III-1E. the improvement in the forecasts using prognostic over analyses steers was near 17 miles, however the number of cases involved was relatively small.

The application of the history correction as describe in section 3, showed considerable improvement in the Monterey steers. As noted in table III-1F, average errors decreased from 148 to 120 miles for the 700 mb level and 181 to 131 miles for the 500 mb level. It seems reasonable that this type of correction could be applied to other objective forecasting techniques, thereby decreasing forecast errors.

Late in the typhoon season, after determination of the best steering level and how to best apply the history correction, the Monterey 700 mb A Modified technique was tested under operational conditions. Although the number of cases was again relatively small, the results, table III-1G, were comparable in accuracy to the JTWC forecast.

5. Concluding Remarks

Of the 14 tropical cyclone steering methods tested, four showed superior verifications. These were the Monterey 700 mb P Modified, Monterey 700 mb P, extrapolation and Monterey 700 mb A Modified.

If the prognostic SR steers can be made available prior to the issuance of the official warning, they will be of considerable value as an easily used and highly accurate forecasting aid. In addition, use of the history modification technique further reduces the forecast errors by a significant amount. Until such time as prognostic SR steers are available, the history modified analyses SR steers provide one of the best objective forecasting techniques available.

Several limitations of the SR steers were noted during the 1967 season. If the tropical cyclone is of considerable size, greater than 800 miles in diameter, it appears that the SR fields are not sufficiently smoothed. The end result is that the cyclone is steered around its own circulation. A second limitation occurs when the cyclone location is south of 10 degrees north latitude. It is felt that the poor steers resulting in these cases were associated with the treatment of the coriolis parameter in the lower latitudes.

B. A NOTE ON THE STAGE C - "COMMA CONFIGURATION"

MAJOR ROBERT W. FETT, USAF
54th Weather Reconnaissance Squadron
Andersen AFB, Guam, Mariana Islands

Numerous examples have been collected which testify to the general validity of the model of tropical cyclone formation described by the author in 1964 [1] . (See figure III-6). Two examples showing a Stage B and a Stage C "Comma Configuration" are displayed in figures III-7 and III-8 respectively. Maximum wind speeds reported for the Stage B depression in the Gulf of Mexico were 20 knots and for the formative stage of Marie shown in figure III-8 reported values of 30 knots were obtained. These values are in excellent agreement with the model shown in figure III-6.

In figure III-9 an example of a storm which does not fit the model is shown. Pronounced banding of low cloudiness north of the major overcast area suggests a center of circulation very near 27.8N and 60.3W. This position is on the edge of the bright overcast cloudiness. The center is embedded by less than 1/2 degree within the overcast cloudiness and hence the storm cannot be classified as to intensity according to the scheme of Timchalk, Hubert and Fritz [2] . The storm can be classified as an intense example of a Stage C+ "Comma Configuration". However, maximum wind speed reported by reconnaissance within one hour of the pictures was 70 knots, a value not at all in keeping with the storm's apparent formative structure.

A few examples of similar storms with unusually high winds have been noted during the past several years of satellite observations. Until now these storms have been considered oddities and no explanation has been suggested to account for the deviation from the normal pattern.

On the 5th of July 1967 the author flew a reconnaissance mission into what was thought to be a formative tropical cyclone. ESSA II pictures of the storm (Billie) on July 4, 1967 at 2320 GMT are shown in figure III-10. The center of circulation of the storm is apparent on the north side of overcast cloudiness near 16.5N, 128E. The storm has the appearance of a Stage C, Comma Configuration and therefore maximum winds of about 30 knots were anticipated. Instead, as the aircraft approached the center, wind speeds of 70 to 80 knots were suddenly encountered. The "eye" of the storm was formed by swirling masses of flattened cumulus and stratocumulus. A picture of the eye taken by the author on 5 July at 0330 GMT is shown in figure III-11. The aircraft's altitude was 10,200 feet. Tops of these clouds were about 4,000 feet. In the area of the eye, no higher cloudiness and certainly no wall cloud in the conventional sense existed. All convective cloudiness of importance lay at least 30

miles to the south of the storm's center. Yet the storm had a very definite warm core. On the first penetration on July 4th at 2120 GMT, temperatures at the 726 mb level rose from values of 14.1°C a few miles away from the eye to a value of 17.2°C directly over the eye. On the second penetration on July 5th at 0330 GMT at 700 mbs temperature rose from values of 13.5°C a few miles outside of the eye to a value of 18.5°C directly over the eye. The temperature rises were noted as the aircraft flew over the eye in perfectly clear, cloud-free conditions. This, then was the key to an understanding of why the storm was so intense. Somehow it had become "warm-core" without ever developing a wall-cloud. Turning back to figure III-9 it can be seen that the eye of this storm was also apparently formed only by low cloudiness. Note the shadow of upper-cloudiness falling on the low clouds which swirl about the eye.

How can a warm core be established in a storm which does not have a wall-cloud? The obvious answer is through forced descent of upper-tropospheric air into the storm's center, resulting in warming through compression. The storm could not have become warm core through ascending motion and release of latent heat near the eye. Any upward motion in such a moist environment would surely have produced significant cloudiness of great vertical development and this was not observed. On the contrary, low cloudiness present was flattened and suppressed. What mechanism could cause forced descent of upper tropospheric air into the narrow region around the eye? A most probable answer is low level divergence. If the winds about the storm center (which we may assume was initially cold core) were through some mechanism to become super-gradient, then cyclonic outflow and evacuation of air would occur from the storm center at low levels. Descending air from higher levels would be required by continuity followed by warming through compression. A lowering of pressure would occur because of the warming and the pressure gradient force into the storm center would be increased. Winds now swirling about the storm center would suddenly become sub-gradient and converge toward the storm center. But by conservation of angular momentum as they converged toward the center their speeds would increase until they were again super-gradient. In this manner pulsating between super-gradient and sub-gradient wind speeds would gradually increase until some upper limit was reached and steady state attained. Based on the sample of storms viewed over the past several years including three storms similar to Billie which the author has flown into, this upper limit appears to be about 70 to 80 knots. Storms of greater intensity invariably have a wall-cloud over a large segment around the eye.

It is easily seen why storms which do have a wall-cloud can become more intense. The upper limit in a storm of the Billie variety is necessarily prescribed by the temperature of the undisturbed high level tropospheric air drawn down into the eye. Higher temperatures in storms with wall-clouds must be attributed to forced warming of air already

C. FORECASTING DEVELOPMENT OF TROPICAL CYCLONES

A method to forecast formation of Tropical Cyclones was formulated using conventional synoptic data and local APT cloud pictures. 200 mb synoptic data were used to determine potential development 72 hours in advance and surface and 700 mb data were used to forecast development in 48 hours or less. The four basic types of formation in this method are:

1. Type 1A: Vortex in the Intertropical Convergence Zone (ITC) or in the basic easterly low level wind flow during the summer.
2. Type 1B: Vortex in the low level southwesterly monsoon during summer.
3. Type 2: Vortex embedded in the basic southerly low level "feeding" into another storm, during summer.
4. Type 3: Vortex in the ITC or in the basic easterly low level wind flow during winter.

The following methods were used to forecast formation.

1. 72 hour outlook:

- a. If Mid-Pacific Trough or other major troughs at 200 mbs are absent west of 175E: Typhoon formation unlikely: Only type 1B in the South China Sea and type 2 which is relatively rare should occur.
- b. If Mid-Pacific Trough is present north of 15N, Type 1A formation possible during summer in an area between 25N - 15N and 135E - 170E.
- c. If Mid-Pacific Trough is present south of 15N, Type 1A formation possible during summer in an area between 15N - Equator and 135E - 175E. Type 3 formation possible during winter in an area between 10N - Equator and 135E - 160E.

2. 24 to 48 hour forecast:

- a. Inspect current surface streamline analysis and locate lows of the 4 types:

(1). During summer:

- (a). Type 1A vortex embedded in the easterlies south of 15N.

(b). Type 1B (in the South China Sea) vortex embedded in the low level southwest monsoon flow with easterlies to the north of it.

(c). Type 2 vortex to the east or south of a typhoon.

(2). During winter:

(a). Type 3 vortex embedded in the easterlies south of 10N with the following synoptic pattern.

/1/. Veering of wind at nearby island station.

/2/. Cyclonic turning of wind flow into southern hemisphere.

/3/. Shearline approaching vortex from the northwest.

b. Inspect current 700 mb streamline analysis and locate lows of the 4 types:

(1). During summer:

(a). Type 1A vortex south of 15N in the easterly flow.

(b). Type 1B (in the South China Sea) vortex present if Clark AFB, Philippine's wind is southerly and Vietnam's wind is northerly or westerly.

(c). Type 2 low to east or south of a typhoon.

(2). During winter:

(a). Type 3 low south of 10N with trough oriented east-west slightly north of the equator.

(b). Tropical depression not possible if low clouds are absent.

c. Inspect current APT cloud pictures.

(1). If there are no significant overcast cloud systems south of 25N, no Tropical Depression possible.

(2). During summer, with a surface and 700 mb low present, the cloud pictures will verify the existence of a low and show its stage of development. The four cloud pictures (figures III-12 through III-15) illustrate the important features to observe.

In summary, this article is not all conclusive for forecasting tropical cyclone development. Other types exist, however, the four types discussed above were the ones most frequently observed during the 1967 season.

Figure III-12

TYPE 1A:

1. Almost circular overcast cloud mass (core).
2. Major overcast cloud mass (bands) located south of center.
3. Cloud bands turning cyclonically into overcast cloud mass.
4. Cirrus blow-off from tops of overcast clouds.

Figure III-13

TYPE 1B in the South China Sea:

1. Cloud bands oriented parallel to the southwest monsoon flow.
2. Small central overcast cloud mass (core).
3. Cyclonic turning of cloud bands into overcast mass.
4. Cirrus blow-off towards west.

Figure III-14

TYPE 2:

1. Cut-off overcast cloud mass (core) from the southerly low level wind flow into another storm to north or west.
2. Cyclonic turning of smaller cloud bands into center.
3. Cirrus blow-off.
4. Major cloudiness to the south of center.

Figure III-15

TYPE 3:

1. Overcast cloud mass forming in ITC.
2. Overcast cloud mass (core).
3. Major cloud mass (bands) to the south of center.
4. Cyclonic turning of cloud bands around center.
5. Shearline approaching center from the north.
6. Cirrus blow-off.

D. AN EXAMPLE OF TWO VORTICES WITHIN A LARGE TROPICAL SYSTEM

During the two week period of 14 to 28 July, 1967 several interesting aspects of tropical cyclone behavior occurred in the Western Pacific. The period began with an undesignated tropical low forming southwest of Guam in the ITCZ. This low moved northwest through the Ryukyu Islands and into the Yellow Sea, resulting in a break in the subtropical ridge in the Ryukyu Islands area by 20/0000Z. However, the ridge remained strong eastward from Japan. Then followed the development of a large tropical system, which included Tropical Storm DOT and Tropical Depression NINE in the area of Guam, as noted on synoptic charts and APT cloud pictures. The ultimate movement of this system was also toward the northwest, following nearly the same track as that of the previous cyclone into the Yellow Sea.

Between 20/0000Z and 21/0000Z T.S. DOT and T.D. Nine were fixed by reconnaissance aircraft and warnings were issued on the two systems. The two centers began interacting as they moved cyclonically toward one another; T.D. Nine curved from a northerly to a westerly track while DOT moved eastward, figure III-16A.

During the period 21/0000Z to 22/0000Z the two centers appeared to undergo a partial Fujiwhara rotation. T.D. Nine, moving westward, passed about 200 miles north of T.S. DOT, while the latter curved toward the north. During this period DOT developed quite rapidly in intensity and became a very large circulation; for example, at 22/0000Z its surface circulation pattern extended 900 miles from north to south and 1100 miles from east to west. DOT's maximum observed surface wind speed reached 50 kts at this time while T.D. Nine remained weak but still had a distinct center as reported by reconnaissance aircraft and as shown by APT pictures, figure III-16B.

By 23/0000Z T.D. Nine became absorbed into the large circulation of T.S. DOT. DOT's circulation remained very large through 25 July as indicated by satellite pictures, reconnaissance data, and surface reports, figure III-16C.

Throughout the period 22 to 26 July the remnants of T.D. Nine appeared to track along as a secondary center in DOT's circulation. Because of the large size of the overall circulation, the relative weakness of the storm, and the presence of the secondary center, this was a difficult period for both the forecasters and the reconnaissance missions. It was decided that the most meaningful "best track" for this period, as determined from post-analysis, would be the track of the geographical center of the overall circulation. As can be seen from the fix positions for DOT, the most

consistently fixed center, and apparently the most intense, was that to the north of the mean track, while a second center, the remnant of T.D. Nine, followed along to the south, figure III-16D. As DOT passed southern Japan its center became well-defined, the circulation became much smaller, and it reached its greatest intensity. After this, DOT was fixed consistently as one distinct center as it followed a northwesterly track into the Yellow Sea where it became extratropical.

During 1967 the Joint Typhoon Warning Center issued a total of 957 tropical warnings on 20 typhoons, 15 tropical storms and six tropical depressions. Warnings were issued on two or more tropical cyclones simultaneously on a total of 62 calendar days; on 17 of the 62 days three tropical cyclones were in existence.

The following data for the JTWC area of responsibility is presented for comparison:

TOTAL TROPICAL CYCLONES	30	42	39	28	45	40	38	41

In the area of the North Pacific Ocean east of 180 degrees, 474 warnings were issued on a total of 20 tropical cyclones (See Annex A). One tropical cyclone, SARAH, developed in the area between 150 degrees and 140 degrees west and tracked across the dateline into JTWC's area of responsibility. This necessitated the transfer of a cyclone from JHWC, Hawaii, to FWC/JTWC. The track of SARAH (4499 MI) was the longest in history.

There were four "Super Typhoons" (maximum sustained surface winds of 130 knots or greater) compared with three during 1966 and a record of 11 during 1965. The most intense storm of 1967 was Typhoon Carla (12-20 Oct) with maximum sustained surface winds of 160 knots. The minimum sea level pressure of 901 mb and the minimum 700 mb height of 2170 meters were observed at 142138Z. The maximum wind was observed over water, although considerable damage to property resulting from flooding occurred as CARLA tracked westward over Northern Luzon with sustained surface winds of near 100 knots.

Examples of the Fujiwhara effect were exhibited by Typhoons Marge and Nora during August, and Tropical Storm Dot and Tropical Depression Nine during July. Dot was a well-documented case of secondary eyes within the same overall circulation of a storm (see Chapter III).

An abnormal number of tropical cyclones developed north of 20 degrees north latitude during the 1967 season. Four typhoons and six tropical storms fell into this category.

As in other years, the 24, 48, and 72 hour mean forecast error for each typhoon was computed by two methods. In addition to the standard mean forecast error (Tables IV-1 and IV-2), a computation of closest-distance (right angle) error from best track (Table IV-3) has been included for comparison. This error computation is based on the closest right angle distance of the forecast position to the best track without regard to time.

Note: The positions in Tropical Storm Position Data are for periods of tropical storm intensity only; i.e., where the best track showed the intensity to be greater than 33 knots.

The following tabulation of the average forecast error for the past 18 years is given for comparison:

TABLE IV-3

To better understand the areas in which larger or smaller errors occur, the mean errors are tabulated with respect to latitude for the 24, 48 and 72 hour forecast positions (Table IV-4). Also, distances from positions given in the bulletins versus the best track positions is summarized (Table IV-5). Possibly this information will give the user a better understanding of the ability of JTWC to forecast the effects of a typhoon in a particular area.

The statistics, fix data and verification pages for each typhoon have been automated and are identified by cyclone number.

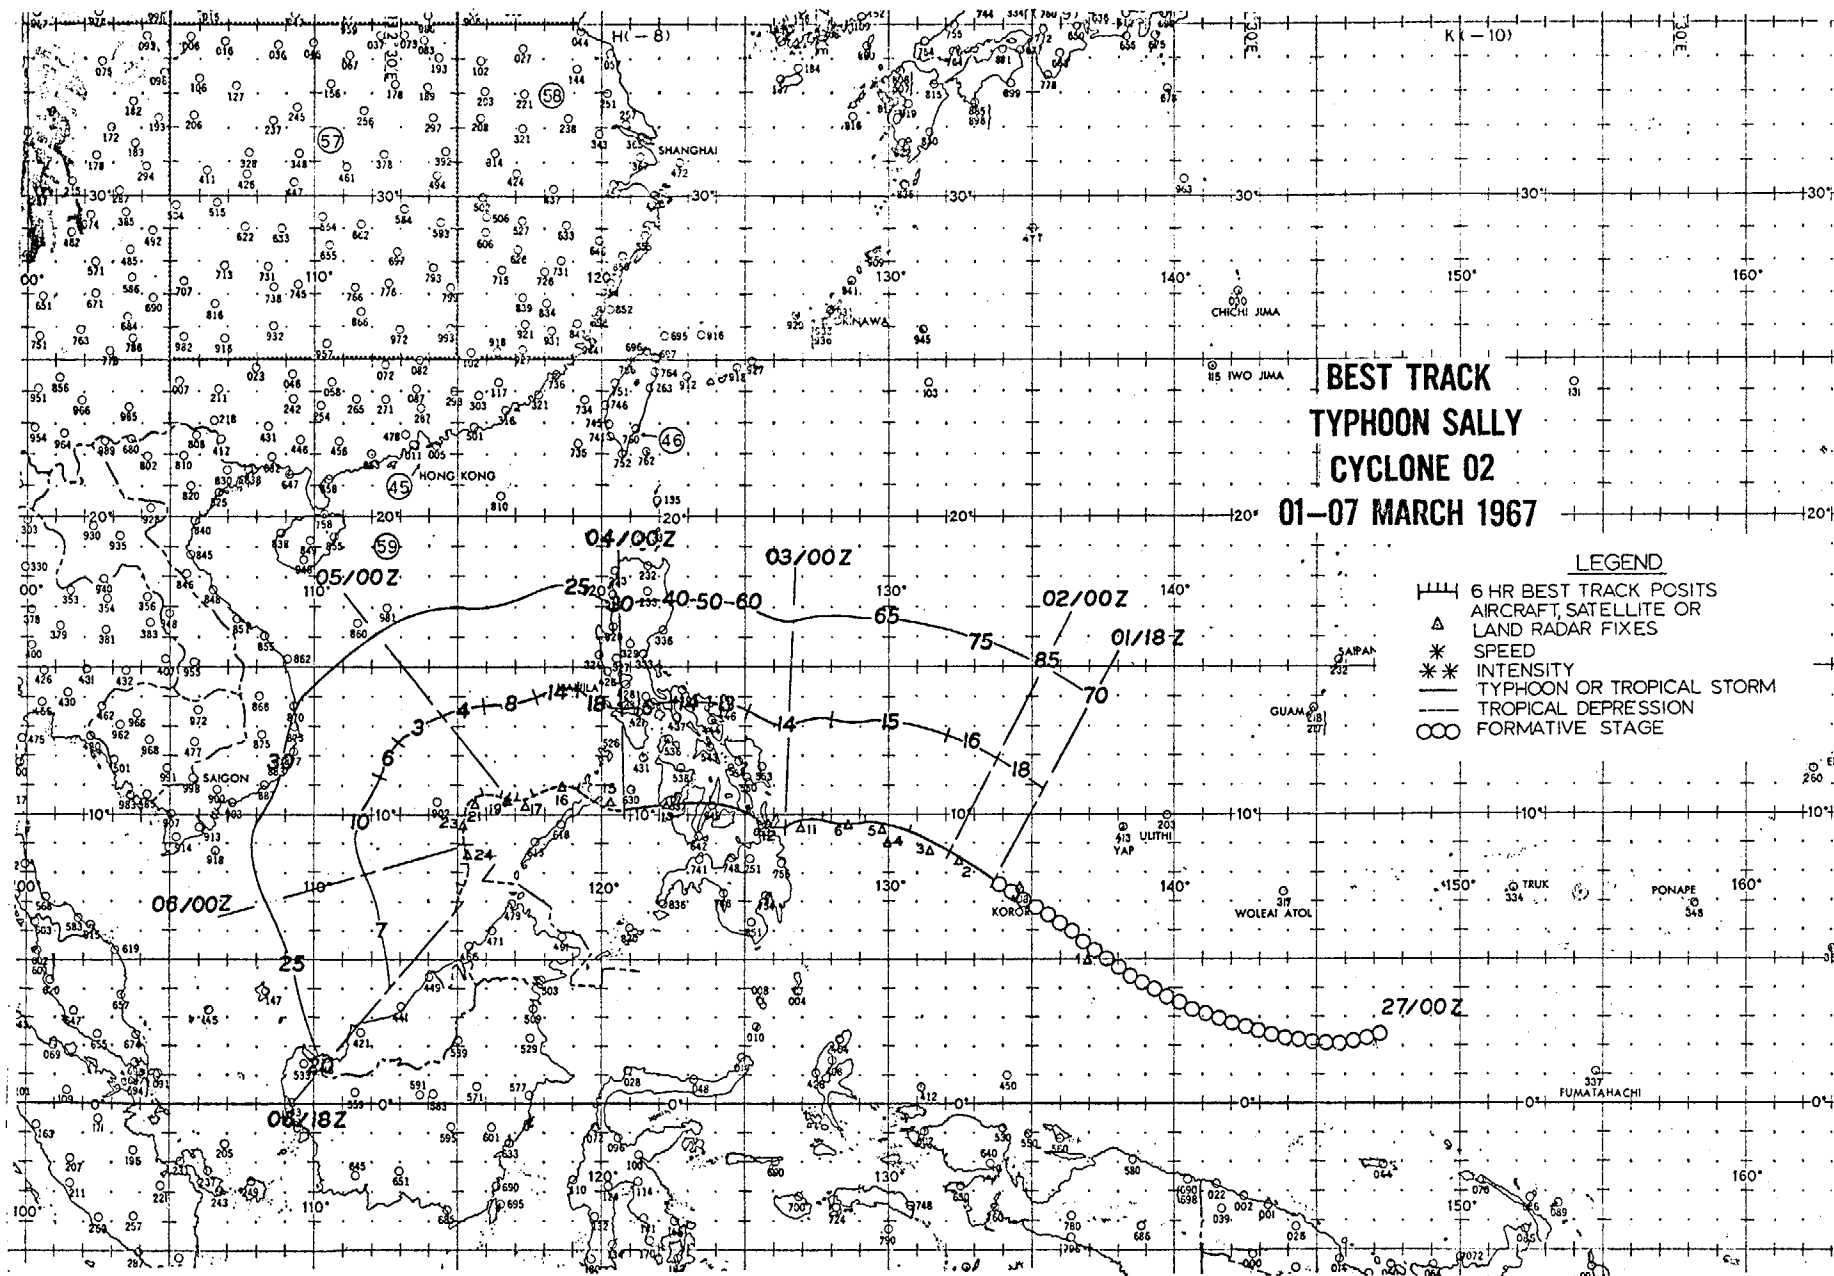

For convenience a list of cyclone numbers versus typhoon names follows:

<u>CYCLONE</u>	<u>NAME</u>
02	SALLY
04	VIOLET
06	ANITA
07	BILLIE
08	CLARA
12	ELLEN
21	KATE
22	MARGE
24	NORA
25	OPAL
27	RUTH
28	SARAH
31	WANDA
32	AMY
35	CARLA
36	DINAH
37	EMMA
38	FREDA
39	GILDA
40	HARRIET

See Appendix A for definitions or clarification of certain words and phrases that appear in this chapter.

TROPICAL CYCLONE 02 - 03/01/1800Z TO 03/07/0000Z

- I. DATA
 - A. STATISTICS
 1. NUMBER OF WARNINGS ISSUED - 22
 2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 09
 3. TOTAL DISTANCE TRAVELED DURING TROPICAL WARNING PERIOD - 1374 MI
 - B. CHARACTERISTICS AS A TYPHOON
 1. MINIMUM OBSERVED SLP - 971MBS AT 020230Z
 2. MINIMUM OBSERVED 700MB HEIGHT - 2493M. AT 012330Z
 3. MAXIMUM SURFACE WIND - 085 KTS (FROM BEST TRACK)
 4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 180 MI
- II. DEVELOPMENT
 - A. INITIAL IMPETUS - FRACTURE OF A POLAR TROUGH AND AN EASTERLY WAVE
 - B. INITIAL SURFACE VORTEX
 1. EMHEDDED VORTEX AT 270000Z
 2. SURFACE PRESSURE LESS THAN 1006MB
 - C. 200MB FLOW ABOVE SURFACE VORTEX
 1. INITIAL - SOUTHEAST
 2. UPON REACHING TYPHOON INTENSITY - SOUTHEAST
- III. FINAL DISPOSITION - DISSIPATED OVER WATER

TROPICAL CYCLONE 04 - 04/01/0600Z TO 04/12/0600Z

- I. DATA
 - A. STATISTICS
 1. NUMBER OF WARNINGS ISSUED - 45
 2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 32
 3. TOTAL DISTANCE TRAVELED DURING TROPICAL WARNING PERIOD - 2688 MI
 - B. CHARACTERISTICS AS A TYPHOON
 1. MINIMUM OBSERVED SLP - 929MBS AT 060825Z
 2. MINIMUM OBSERVED 700MB HEIGHT - 2460M. AT 060825Z
 3. MAXIMUM SURFACE WIND - 120 KTS (FROM BEST TRACK)
 4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 450 MI
- II. DEVELOPMENT
 - A. INITIAL IMPETUS - FRACTURE OF A POLAR TROUGH AND AN EASTERLY WAVE
 - B. INITIAL SURFACE VORTEX
 1. INDUCED VORTEX AT 301200Z
 2. SURFACE PRESSURE LESS THAN 1004MB
 - C. 200MB FLOW ABOVE SURFACE VORTEX
 1. INITIAL - EAST
 2. UPON REACHING TYPHOON INTENSITY - EAST
- III. FINAL DISPOSITION - DISSIPATED OVER WATER

09/00Z-11/00Z APRIL 1967

TROPICAL CYCLONE 06 - 06/26/0600Z TO 06/30/0600Z

- I. DATA
 - A. STATISTICS
 - 1. NUMBER OF WARNINGS ISSUED - 17
 - 2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 10
 - 3. TOTAL DISTANCE TRAVELED DURING TROPICAL WARNING PERIOD - 1164 MI
 - B. CHARACTERISTICS AS A TYPHOON
 - 1. MINIMUM OBSERVED SLP - 967MBS AT 281600Z
 - 2. MINIMUM OBSERVED 700MB HEIGHT - 2696M. AT 281600Z
 - 3. MAXIMUM SURFACE WIND - 080 KTS (FROM BEST TRACK)
 - 4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 415 MI
- II. DEVELOPMENT
 - A. INITIAL IMPETUS - LOW LEVEL SURGE INTO CYCLONIC CIRCULATION FROM THE SOUTH WITH SUBSEQUENT DIVERGENCE AT 200MB LEVEL
 - B. INITIAL SURFACE VORTEX
 - 1. JUNCTION VORTEX AT 240000Z
 - 2. SURFACE PRESSURE LESS THAN 1008MB
 - C. 200MB FLOW ABOVE SURFACE VORTEX
 - 1. INITIAL - NORTHEAST
 - 2. UPON REACHING TYPHOON INTENSITY - NORTHEAST
- III. FINAL DISPOSITION - DISSIPATED OVER LAND

AVERAGE 24 HOUR ERROR - 0136 MI.

AVERAGE 48 HOUR ERROR - 0276 MI.

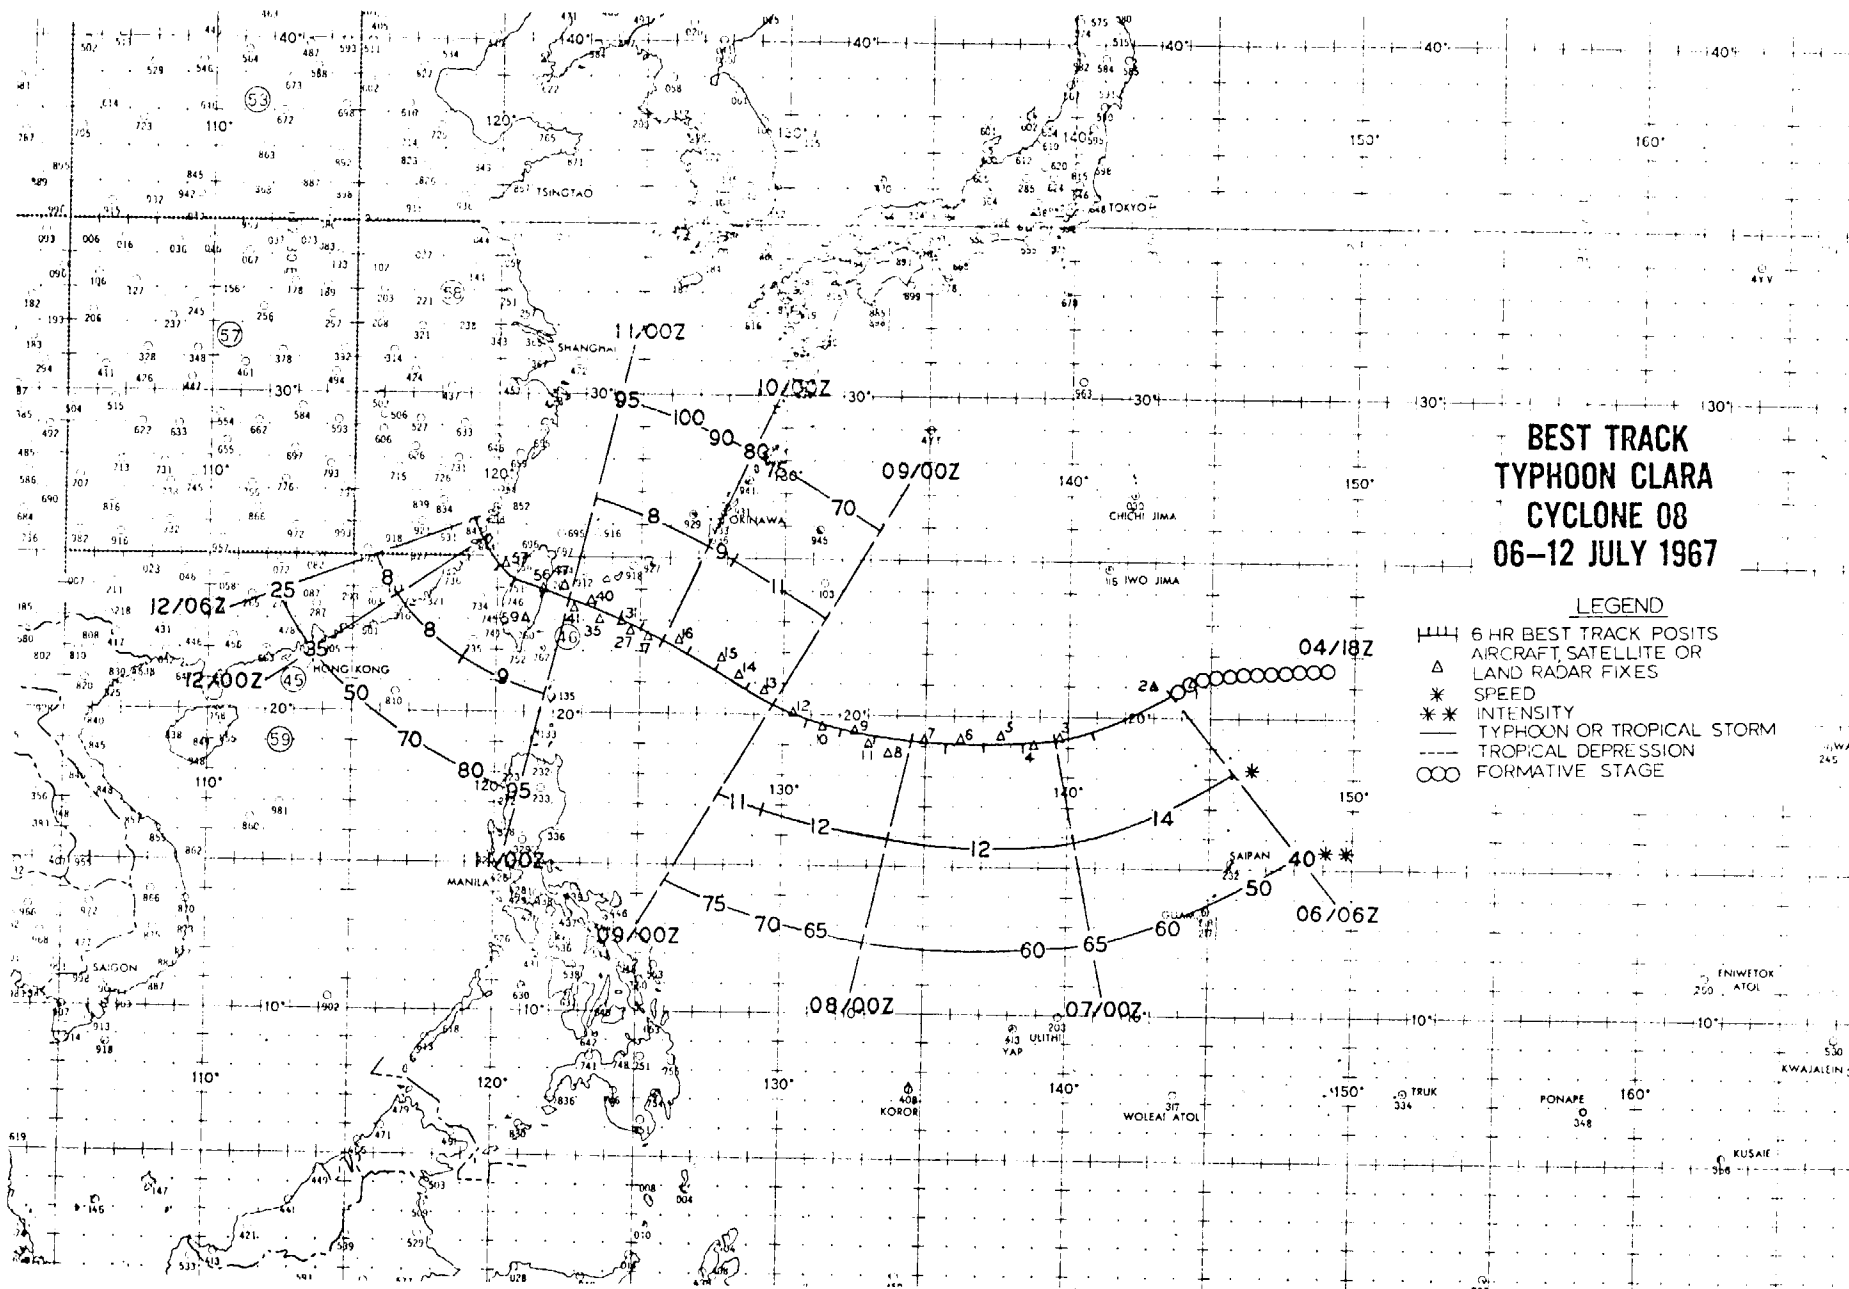

AVERAGE 72 HOUR ERROR - 0254 MI.

TROPICAL CYCLONE 08 - 07/06/0600Z TO 07/12/0600Z

- I. DATA
 - A. STATISTICS
 1. NUMBER OF WARNINGS ISSUED - 25
 2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 19
 3. TOTAL DISTANCE TRAVELED DURING TROPICAL WARNING PERIOD - 1518 MI
 - B. CHARACTERISTICS AS A TYPHOON
 1. MINIMUM OBSERVED SLP - 960MBS AT 102103Z
 2. MINIMUM OBSERVED 700MB HEIGHT - 2426M. AT 100920Z
 3. MAXIMUM SURFACE WIND - 100 KTS (FROM BEST TRACK)
 4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 320 MI
- II. DEVELOPMENT
 - A. INITIAL IMPETUS - A COLD CORE LOW BECOMING WARM CORE AFTER DEVELOPMENT OF DIVERGENCE AT 200MB
 - B. INITIAL SURFACE VORTEX
 1. COLD VORTEX AT 041800
 2. SURFACE PRESSURE LESS THAN 1010MB
 - C. 200MB FLOW ABOVE SURFACE VORTEX
 1. INITIAL - NORTHEAST
 2. UPON REACHING TYPHOON INTENSITY - NORTHEAST
- III. FINAL DISPOSITION - DISSIPATED OVER LAND

TROPICAL CYCLONE 21 - 08/19/0600Z TO 08/21/1200Z

- I. DATA
 - A. STATISTICS
 1. NUMBER OF WARNINGS ISSUED - 10
 2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 03
 3. TOTAL DISTANCE TRAVELED DURING TROPICAL WARNING PERIOD - 0540 MI
 - B. CHARACTERISTICS AS A TYPHOON
 1. MINIMUM OBSERVED SLP - 978MBS AT 202138Z
 2. MINIMUM OBSERVED 700MB HEIGHT - 2935M. AT 210726Z
 3. MAXIMUM SURFACE WIND - 070 KTS (FROM BEST TRACK)
 4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 300 MI
- II. DEVELOPMENT
 - A. INITIAL IMPETUS - MONSOONAL SURGE WITH SUBSEQUENT DEVELOPMENT OF 200MB DIVERGENCE
 - B. INITIAL SURFACE VORTEX
 1. EMBEDDED VORTEX AT 150000Z
 2. SURFACE PRESSURE LESS THAN 1007MB
 - C. 200MB FLOW ABOVE SURFACE VORTEX
 1. INITIAL - EAST
 2. UPON REACHING TYPHOON INTENSITY - NORTHEAST
- III. FINAL DISPOSITION - DISSIPATED OVER LAND

TROPICAL CYCLONE 27 - 09/06/0600Z TO 09/13/1800Z

- I. DATA
 - A. STATISTICS
 1. NUMBER OF WARNINGS ISSUED - 31
 2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 14
 3. TOTAL DISTANCE TRAVELED DURING TROPICAL WARNING PERIOD - 1674 MI
 - B. CHARACTERISTICS AS A TYPHOON
 1. MINIMUM OBSERVED SLP - 939MBS AT 120300Z
 2. MINIMUM OBSERVED 700MB HEIGHT - 2566M. AT 120300Z
 3. MAXIMUM SURFACE WIND - 110 KTS (FROM BEST TRACK)
 4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 350 MI
- II. DEVELOPMENT
 - A. INITIAL IMPETUS - A COLD CORE LOW BECOMING WARM CORE AFTER DEVELOPMENT OF DIVERGENCE AT 200MB
 - B. INITIAL SURFACE VORTEX
 1. COLD VORTEX AT 040600
 2. SURFACE PRESSURE LESS THAN 1010MB
 - C. 200MB FLOW ABOVE SURFACE VORTEX
 1. INITIAL - SOUTH
 2. UPON REACHING TYPHOON INTENSITY - NORTHWEST
- III. FINAL DISPOSITION - BECAME EXTRATROPICAL

TROPICAL CYCLONE 31 - 09/18/0600Z TO 09/24/1200Z

- I. DATA
 - A. STATISTICS
 - 1. NUMBER OF WARNINGS ISSUED - 26
 - 2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 18
 - 3. TOTAL DISTANCE TRAVELED DURING TROPICAL WARNING PERIOD - 1356 MI
 - B. CHARACTERISTICS AS A TYPHOON
 - 1. MINIMUM OBSERVED SLP - 960MB5 AT 211015Z
 - 2. MINIMUM OBSERVED 700MB HEIGHT - 2752M. AT 210330Z
 - 3. MAXIMUM SURFACE WIND - 095 KTS (FROM BEST TRACK)
 - 4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 360 MI
- II. DEVELOPMENT
 - A. INITIAL IMPETUS - DEVELOPMENT OF DIVERGENCE AT 200MB LEVEL OVER SURFACE CYCLONIC CIRCULATION
 - B. INITIAL SURFACE VORTEX
 - 1. JUNCTION VORTEX AT 150000Z
 - 2. SURFACE PRESSURE LESS THAN 1003MB
 - C. 200MB FLOW ABOVE SURFACE VORTEX
 - 1. INITIAL - WEST
 - 2. UPON REACHING TYPHOON INTENSITY - SOUTHWEST
- III. FINAL DISPOSITION - BECAME EXTRATROPICAL

TROPICAL CYCLONE 32 - 09/28/0600Z TO 10/06/0000Z

- I. DATA
 - A. STATISTICS
 1. NUMBER OF WARNINGS ISSUED - 32
 2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 07
 3. TOTAL DISTANCE TRAVELED DURING TROPICAL WARNING PERIOD - 1872 MI
 - B. CHARACTERISTICS AS A TYPHOON
 1. MINIMUM OBSERVED SLP - 961MBS AT 041510Z
 2. MINIMUM OBSERVED 700MB HEIGHT - 2768M. AT 050400Z
 3. MAXIMUM SURFACE WIND - 080 KTS (FROM BEST TRACK)
 4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 500 MI
- II. DEVELOPMENT
 - A. INITIAL IMPETUS - A COLD CORE LOW BECOMING WARM CORE AFTER DEVELOPMENT OF DIVERGENCE AT 200MB
 - B. INITIAL SURFACE VORTEX
 1. COLD VORTEX AT 231200
 2. SURFACE PRESSURE LESS THAN 1010MB
 - C. 200MB FLOW ABOVE SURFACE VORTEX
 1. INITIAL - SOUTHEAST
 2. UPON REACHING TYPHOON INTENSITY - ANTICYCLONIC
- III. FINAL DISPOSITION - BECAME EXTRATROPICAL

TROPICAL CYCLONE 35 - 10/12/0600Z TO 10/20/0000Z

- I. DATA
 - A. STATISTICS
 1. NUMBER OF WARNINGS ISSUED - 32
 2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 20
 3. TOTAL DISTANCE TRAVELED DURING TROPICAL WARNING PERIOD - 2046 MI
 - B. CHARACTERISTICS AS A TYPHOON
 1. MINIMUM OBSERVED SLP - 901MBS AT 142138Z
 2. MINIMUM OBSERVED 700MB HEIGHT - 2170M. AT 142138Z
 3. MAXIMUM SURFACE WIND - 160 KTS (FROM BEST TRACK)
 4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 675 MI
- II. DEVELOPMENT
 - A. INITIAL IMPETUS - LOW LEVEL SURGE INTO CYCLONIC CIRCULATION FROM THE SOUTH WITH SUBSEQUENT DIVERGENCE AT 200MB LEVEL
 - B. INITIAL SURFACE VORTEX
 1. JUNCTION VORTEX AT 091800Z
 2. SURFACE PRESSURE LESS THAN 1006MB
 - C. 200MB FLOW ABOVE SURFACE VORTEX
 1. INITIAL - SOUTHEAST
 2. UPON REACHING TYPHOON INTENSITY - EAST
- III. FINAL DISPOSITION - DISSIPATED OVER WATER

TROPICAL CYCLONE 37 - 10/31/0000Z TO 11/08/0000Z

- I. DATA
 - A. STATISTICS
 1. NUMBER OF WARNINGS ISSUED - 33
 2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 18
 3. TOTAL DISTANCE TRAVELED DURING TROPICAL WARNING PERIOD - 2184 MI
 - B. CHARACTERISTICS AS A TYPHOON
 1. MINIMUM OBSERVED SLP - 908MBS AT 022200Z
 2. MINIMUM OBSERVED 700MB HEIGHT - 5204M. AT 021520Z
 3. MAXIMUM SURFACE WIND - 140 KTS (FROM BEST TRACK)
 4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 550 MI
- II. DEVELOPMENT
 - A. INITIAL IMPETUS - 200MB ANTICYCLONE OVER THE SURFACE CYCLONE
 - B. INITIAL SURFACE VORTEX
 1. JUNCTION VORTEX AT 260000Z
 2. SURFACE PRESSURE LESS THAN 1008MB
 - C. 200MB FLOW ABOVE SURFACE VORTEX
 1. INITIAL - SOUTHEAST
 2. UPON REACHING TYPHOON INTENSITY - NORTH
- III. FINAL DISPOSITION - DISSIPATED OVER LAND

TROPICAL CYCLONE 38 - 11/07/0600Z TO 11/10/0000Z

- I. DATA
 - A. STATISTICS
 1. NUMBER OF WARNINGS ISSUED - 12
 2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 07
 3. TOTAL DISTANCE TRAVELED DURING TROPICAL WARNING PERIOD - 1044 MI
 - B. CHARACTERISTICS AS A TYPHOON
 1. MINIMUM OBSERVED SLP - 971MBS AT 090940Z
 2. MINIMUM OBSERVED 700MB HEIGHT - 2917M. AT 090415Z
 3. MAXIMUM SURFACE WIND - 085 KTS (FROM BEST TRACK)
 4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 250 MI
- II. DEVELOPMENT
 - A. INITIAL IMPETUS - DEVELOPMENT OF DIVERGENCE AT 200MB LEVEL OVER SURFACE CYCLONIC CIRCULATION
 - B. INITIAL SURFACE VORTEX
 1. INDUCED VORTEX AT 061800Z
 2. SURFACE PRESSURE LESS THAN 1006MB
 - C. 200MB FLOW ABOVE SURFACE VORTEX
 1. INITIAL - EAST
 2. UPON REACHING TYPHOON INTENSITY - EAST
- III. FINAL DISPOSITION - DISSIPATED OVER LAND

TROPICAL CYCLONE 40 - 11/17/0000Z TO 11/24/0000Z

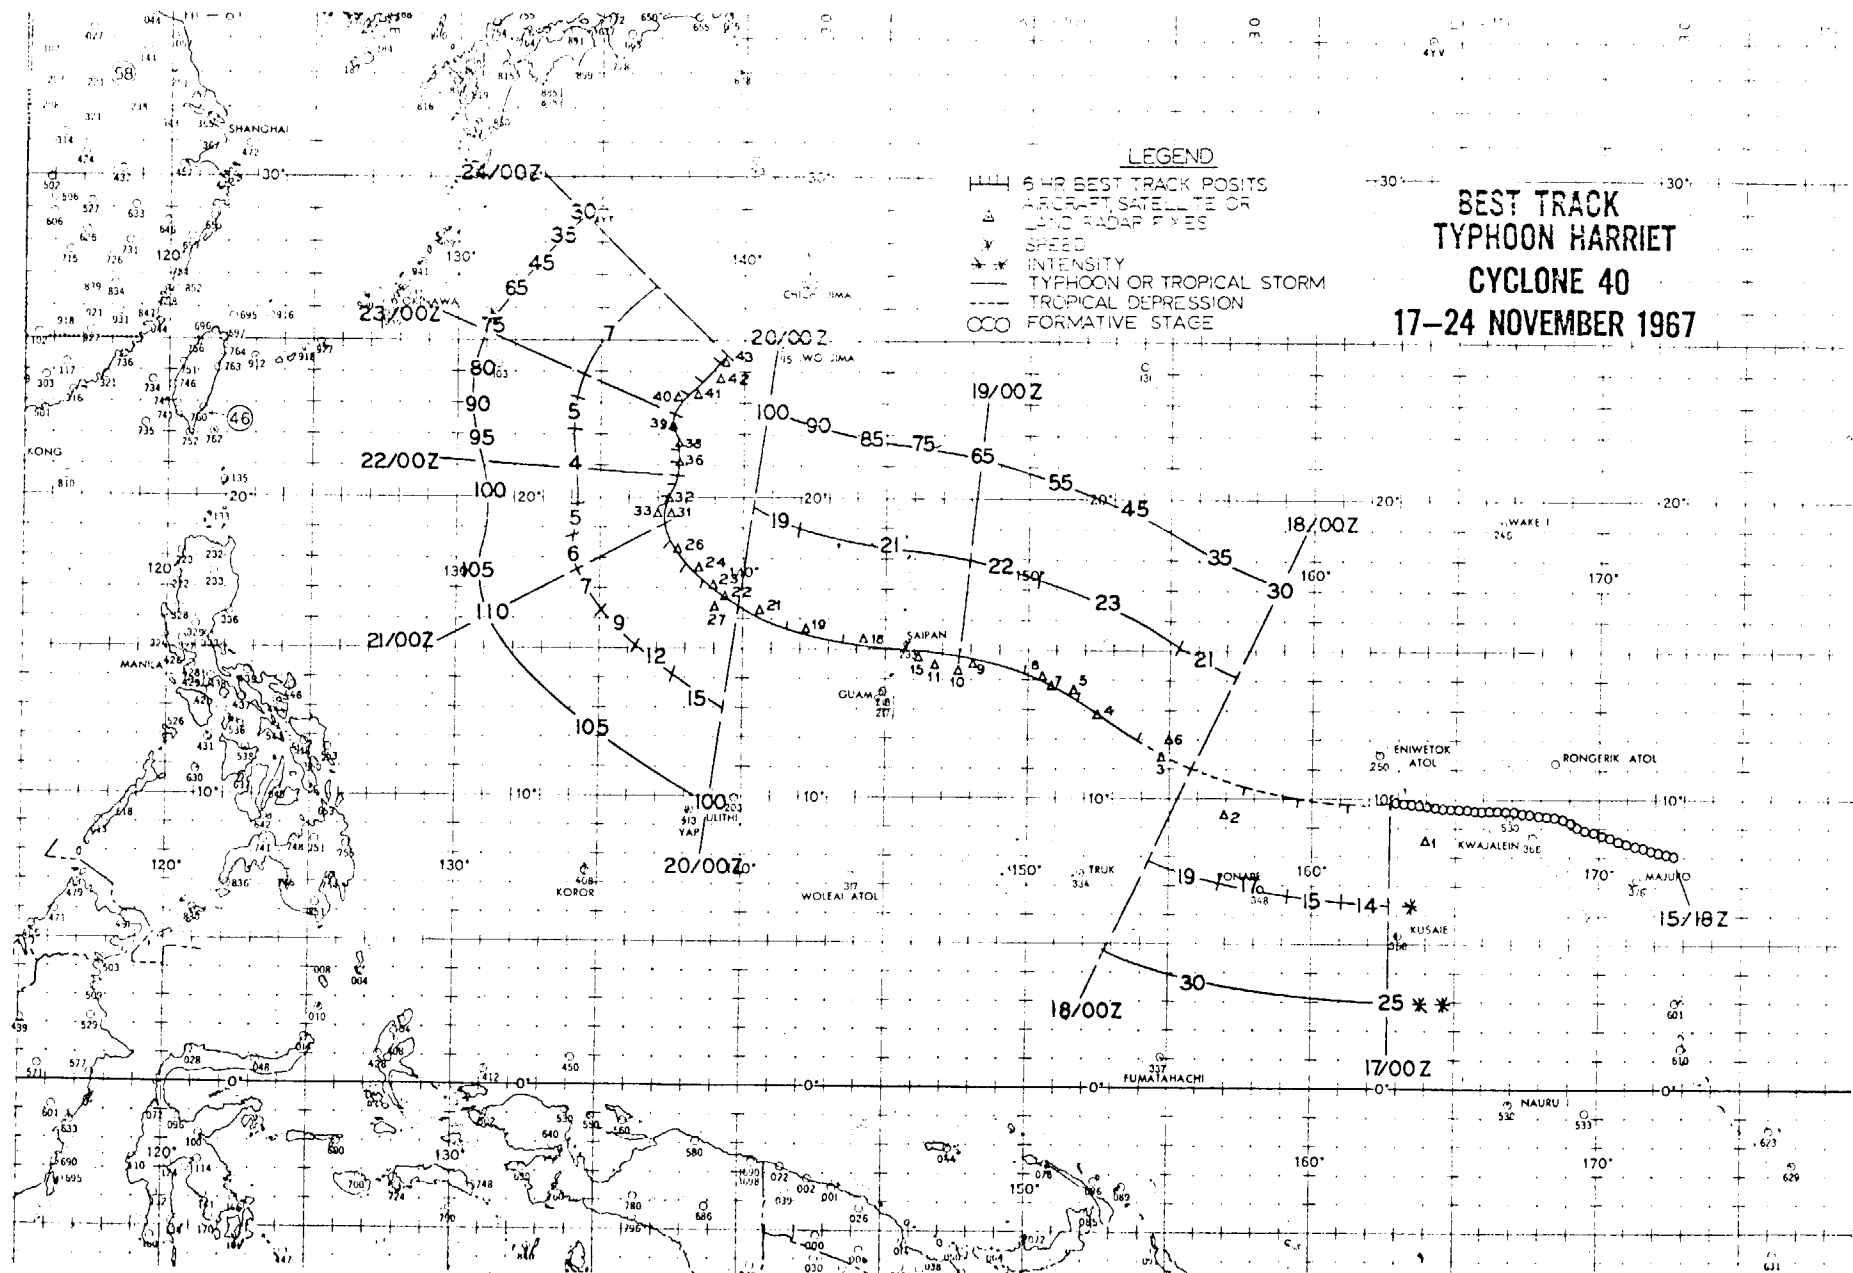

- I. DATA
 - A. STATISTICS
 1. NUMBER OF WARNINGS ISSUED - 29
 2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 15
 3. TOTAL DISTANCE TRAVELED DURING TROPICAL WARNING PERIOD - 2028 MI
 - B. CHARACTERISTICS AS A TYPHOON
 1. MINIMUM OBSERVED SLP - 953MBS AT 202100Z
 2. MINIMUM OBSERVED 700MB HEIGHT - 2891M. AT 202100Z
 3. MAXIMUM SURFACE WIND - 110 KTS (FROM BEST TRACK)
 4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 275 MI
- II. DEVELOPMENT
 - A. INITIAL IMPETUS - LOW LEVEL SURGE INTO CYCLONIC CIRCULATION FROM THE SOUTH WITH SUBSEQUENT DIVERGENCE AT 200MB LEVEL
 - B. INITIAL SURFACE VORTEX
 1. JUNCTION VORTEX AT 151800Z
 2. SURFACE PRESSURE LESS THAN 1007MB
 - C. 200MB FLOW ABOVE SURFACE VORTEX
 1. INITIAL - EAST
 2. UPON REACHING TYPHOON INTENSITY - NORTHEAST
- III. FINAL DISPOSITION - DISSIPATED IN WATER

ANNEX

A

SUMMARY OF TROPICAL CYCLONES

IN THE

EASTERN NORTH PACIFIC OCEAN
(180 DEGREES TO NORTH AMERICAN COAST)

FOR

1967

Fleet Weather Central Alameda and Fleet Weather Central Pearl Harbor issued a record total of 474 tropical warnings on 6 hurricanes, 12 tropical storms and 2 tropical depressions in the Eastern North Pacific during 1967.

The following six year summary covering the Fleet Weather Central Alameda/Fleet Weather Central Pearl Harbor areas is presented for comparison:

SUMMARY OF EASTERN PACIFIC TROPICAL CYCLONE DATA

	<u>1962</u>	<u>1963</u>	<u>1964</u>	<u>1965</u>	<u>1966</u>	<u>1967</u>
TOTAL NUMBER OF WARNINGS*	122	80	60	244	342	474
CALENDAR DAYS OF WARNINGS*	35	26	21	73	70	119
TROPICAL DEPRESSIONS				2	6	2
TROPICAL STORMS	6	5	4	9	6	12
HURRICANES	2	4	2	1	7	6
TOTAL TROPICAL CYCLONES*	8	9	6	12	19	20

*Tropical Depression information not available 1962-1964.

Land strikes on Baja, California were recorded on Hurricane KATRINA and Tropical Storm OLIVIA. Extensive damage, flooding and loss of property resulted in KATRINA's overland passage.

An attempt was made to utilize the Fleet Numerical Weather Facility (FNWF) "Hatrack" steering program as a tool for predicting movement of tropical systems. Both the 700 and 500 mb levels were monitored, but to date results are inconclusive. In addition, a local program utilizing the FNWF "RADFO" is in the development stage. Both programs will be tested extensively during the 1968 season.

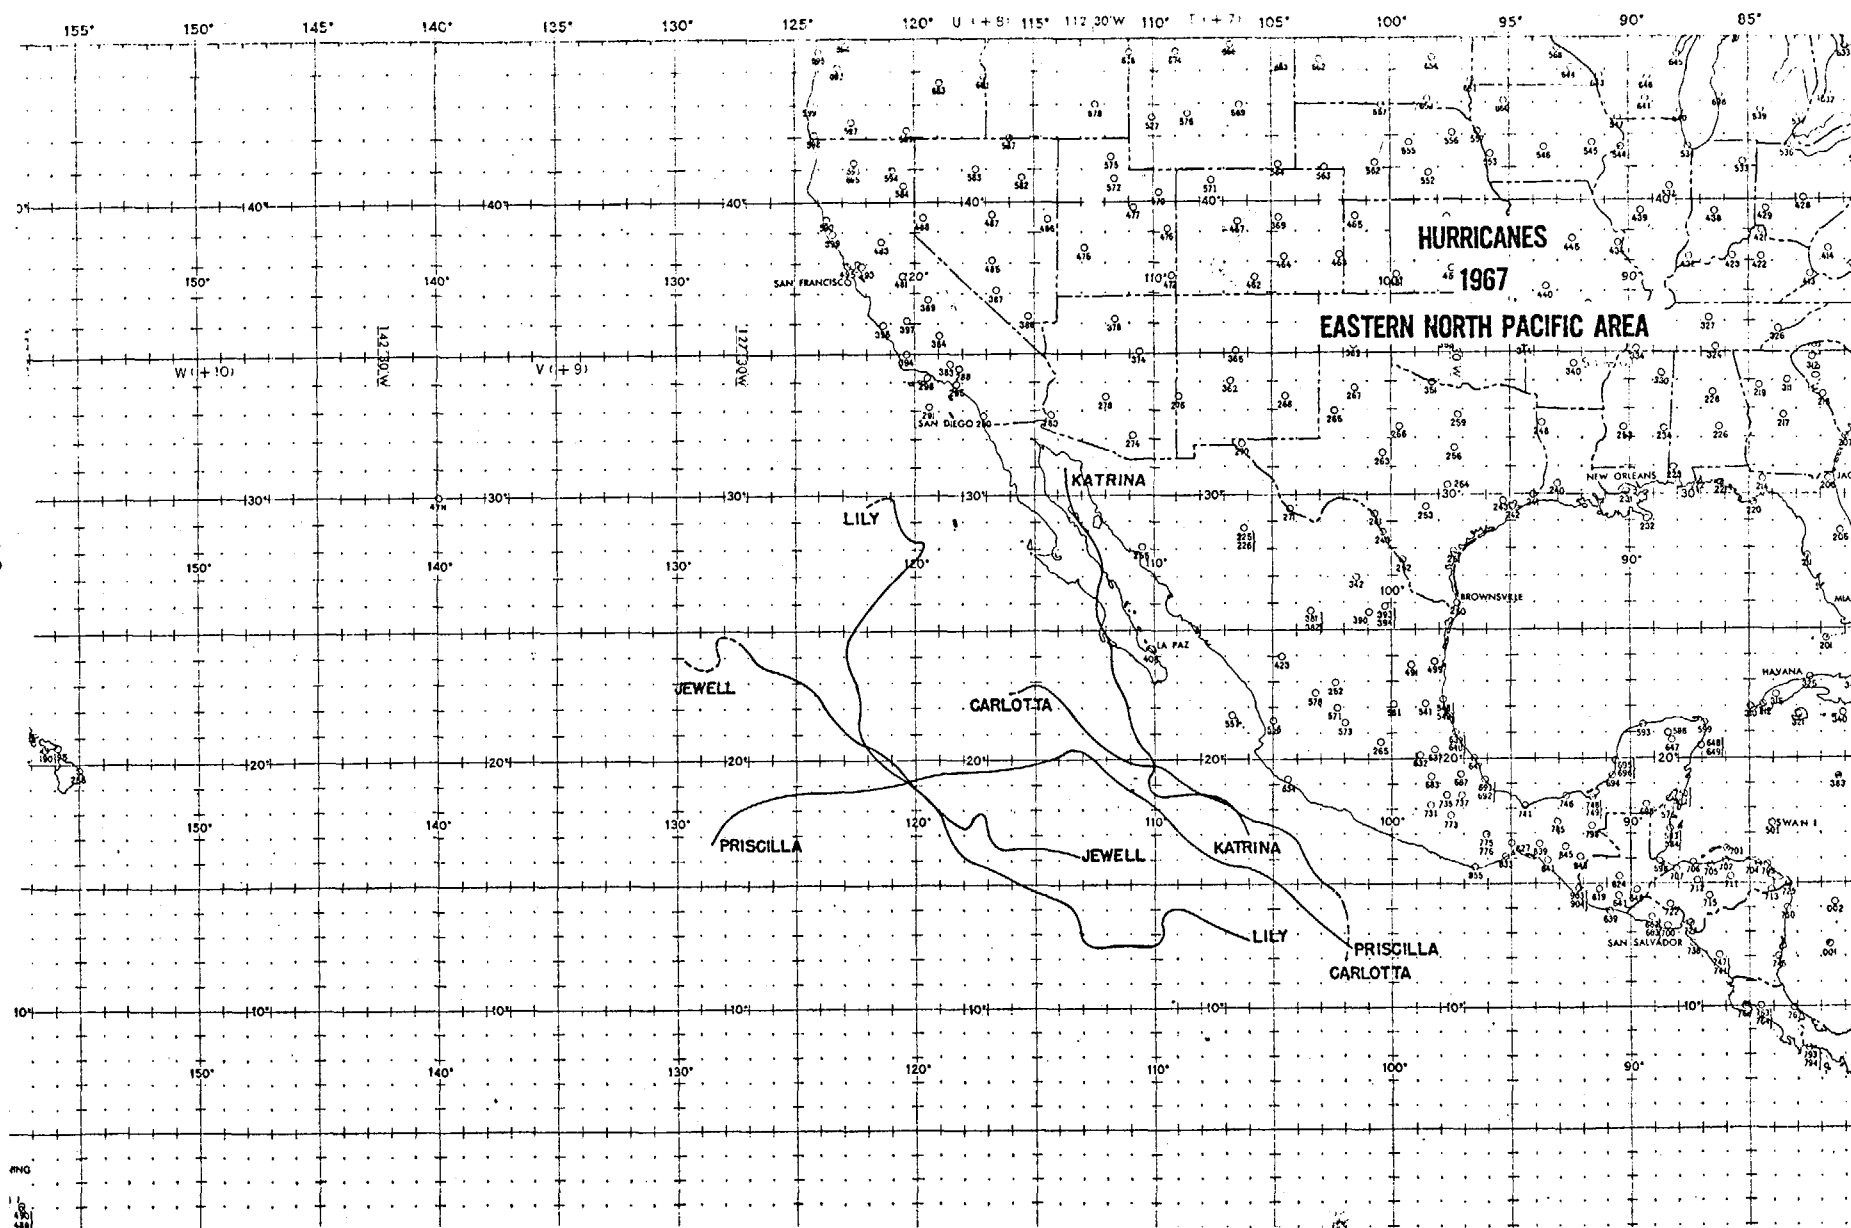

The APT system remains as the primary source of location as shown below in a satellite/recon comparison:

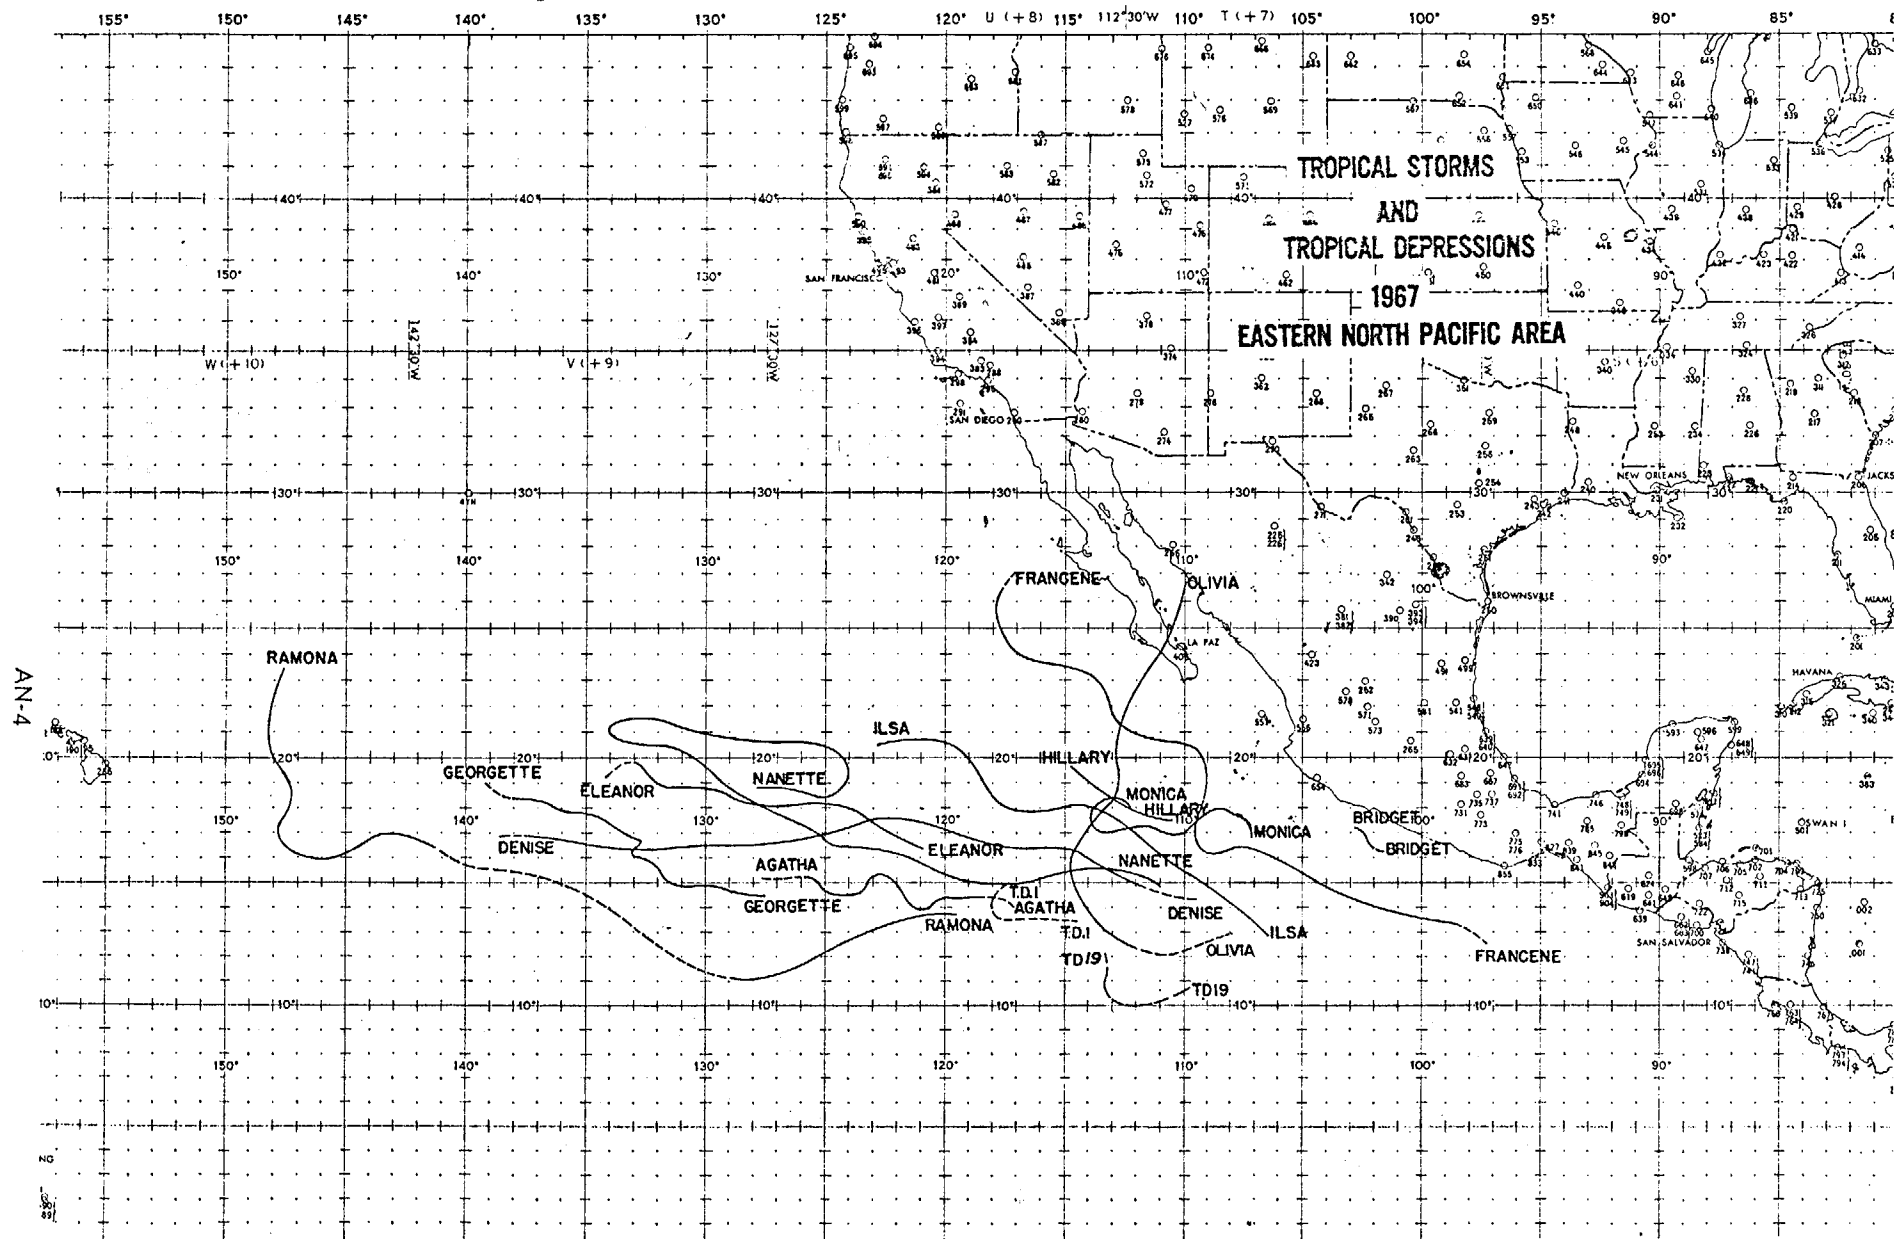

<u>STORM</u>	<u>SATELLITE FIX</u>	<u>RECON FIX</u>
Carlotta	9	1
Jewell	7	5
Katrina	1	2
Lily	15	3
Priscilla	7	1
Sarah	4	8

Antenna location and interference at the ESSA, San Francisco Airport site continues to be a major problem in locating and discerning tropical systems below 20 degrees north latitude. Back up data from PMR Pt. Mugu is most helpful, but descriptions of cloud patterns are verbal and analysts at Fleet Weather Central Alameda are hampered by being unable to actually see the tropical systems on APT readouts.

TROPICAL CYCLONES FOR THE 1967 SEASON

<u>CYCLONE</u>	<u>PERIOD</u>
01. Tropical Depression	18 MAY - 19 MAY
02. Tropical Storm AGATHA	07 JUN - 11 JUN
03. Tropical Storm BRIDGET	15 JUN - 16 JUN
04. Hurricane CARLOTTA	22 JUN - 27 JUN
05. Tropical Storm DENISE	08 JUL - 15 JUL
06. Tropical Storm ELEANOR	13 JUL - 16 JUL
07. Tropical Storm FRANCENE	23 JUL - 28 JUL
08. Tropical Storm GEORGETTE	26 JUL - 30 JUL
09. Tropical Storm HILARY	10 AUG - 11 AUG
10. Tropical Storm ILSA	11 AUG - 16 AUG
11. Hurricane JEWELL	17 JUL - 23 JUL
12. Hurricane KATRINA	29 AUG - 02 SEP
13. Hurricane LILY	04 SEP - 12 SEP
14. Tropical Storm MONICA	13 SEP - 22 SEP
15. Tropical Storm NANETTE	13 SEP - 23 SEP
16. Tropical Storm OLIVIA	05 OCT - 14 OCT
17. Hurricane PRISCILLA	14 OCT - 21 OCT
18. Tropical Storm RAMONA	22 OCT - 03 NOV
19. Tropical Depression	25 OCT - 29 OCT
28. Hurricane SARAH	08 SEP - 14 SEP

Position data for tropical cyclones one through eight were not available at the time of publication. For amplifying information on those storms, contact Fleet Weather Central, Alameda.

HURRICANE "CARLOTTA" - 220600Z TO 270000Z JUNE 1967

I. DATA

A. Statistics

1. Number of warnings issued - 20
2. Number of warnings with hurricane intensity - 8
3. Total distance traveled during tropical warning period - 1030 mi

B. Characteristics

1. Minimum observed SLP - Unknown
2. Minimum observed 700 mb height - UNKNOWN
3. Maximum surface wind - 65 knots
4. Maximum radius of surface circulation - 300 mi

II. DEVELOPMENT

A. Initial impetus - ITCZ

B. Initial surface vortex

1. 220600Z
2. Surface pressure less than 1008mb

C. Time storm reached hurricane intensity - 240000Z

III. FINAL DISPOSITION

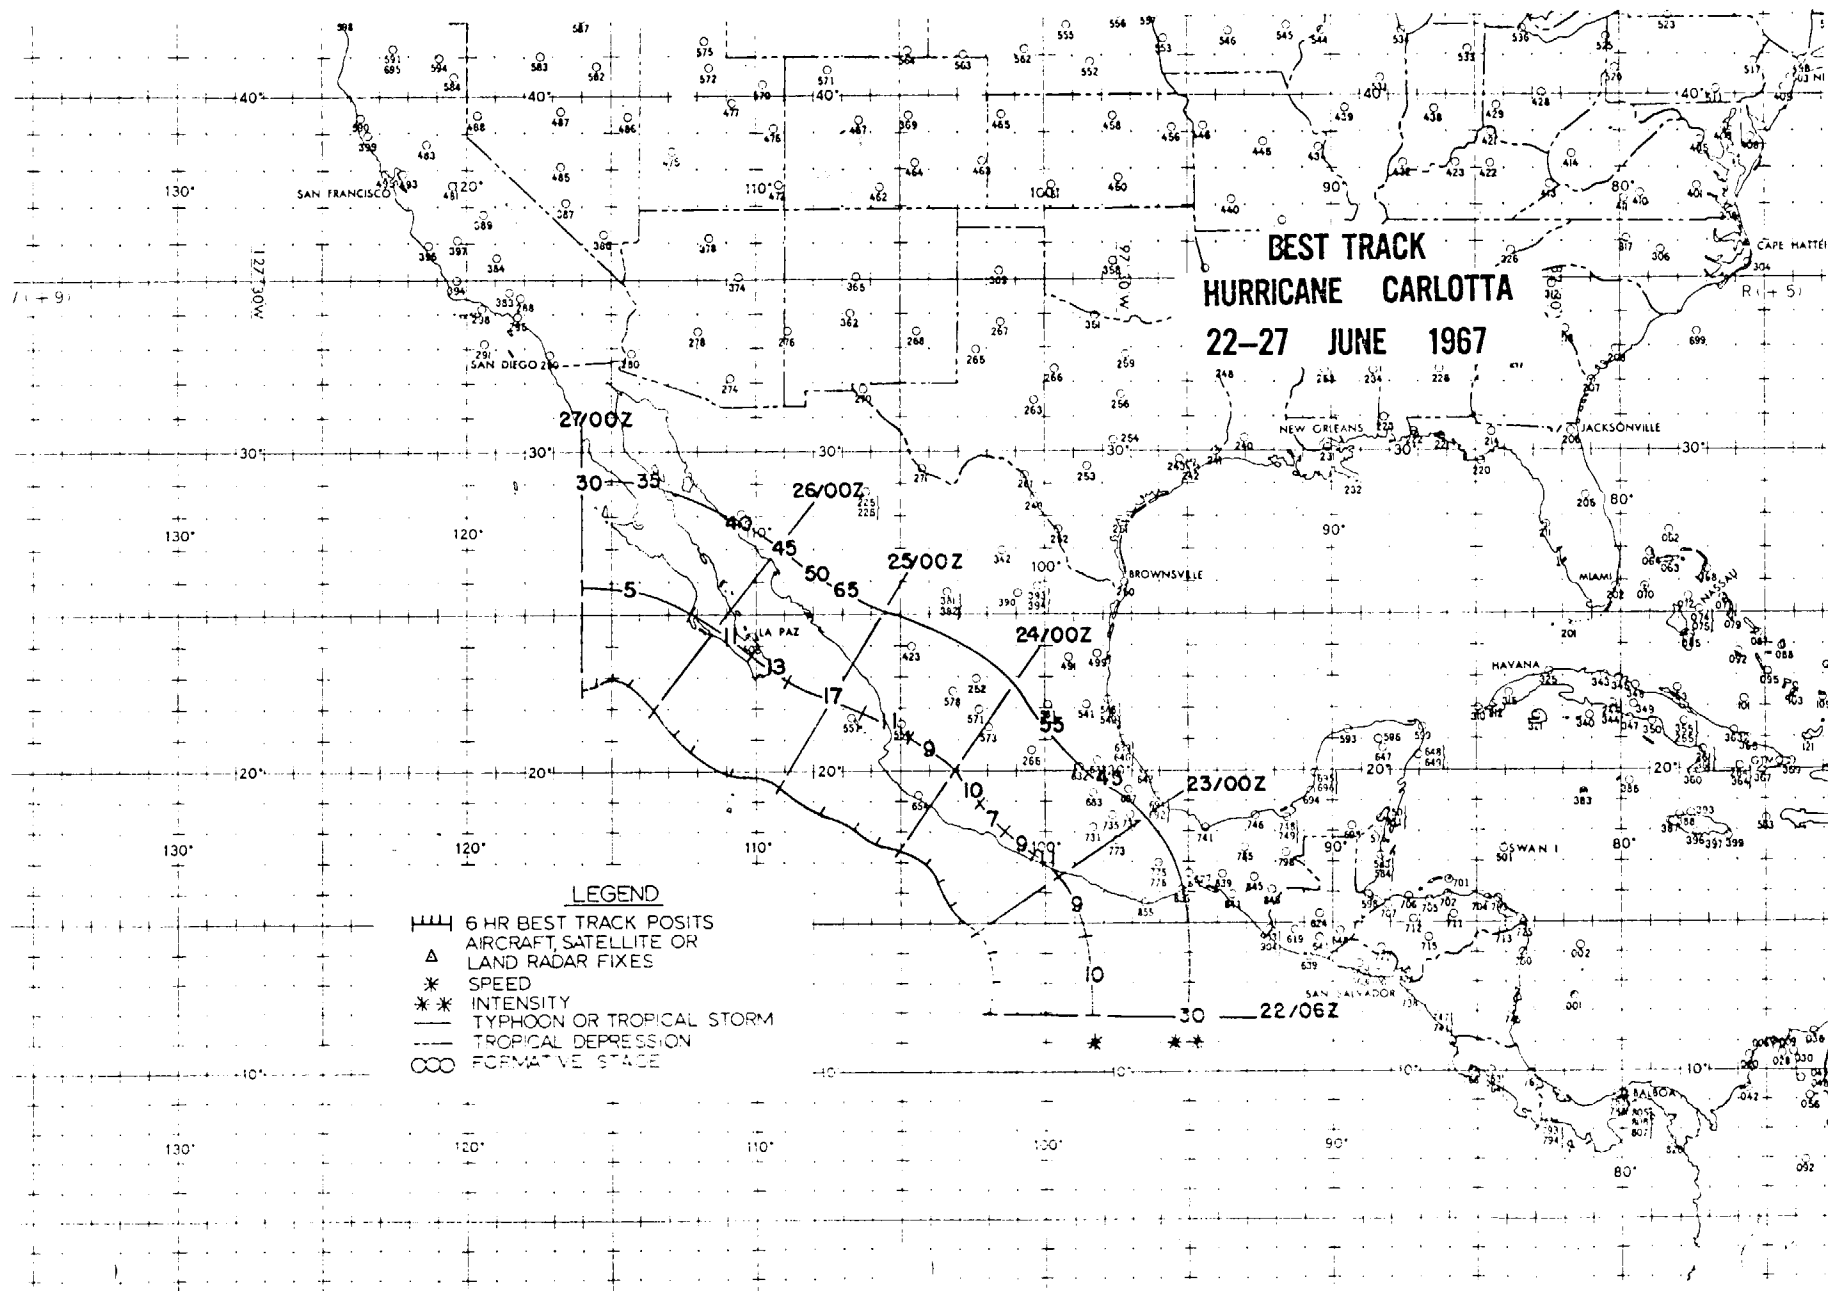

A. Dissipated over water

HURRICANE SARAH - 081800Z to 140000Z September 1967

I. DATA

A. STATISTICS

1. Number of warnings issued in FWC Pearl Harbor's area: 22
2. Number of warnings with hurricane intensity: 4
3. Total distance traveled in FWC Pearl Harbor area: 1925 nautical miles. (as T.S. 1645 nm; as hurricane 280 nm)

B. CHARACTERISTICS AS A HURRICANE

1. Minimum observed slp and 700 mb height: All reconnaissance flights were high level at 300 mb.
2. Maximum surface wind in FWC Pearl Harbor area: 65 knots
3. Maximum radius of surface circulation: 500 nautical miles

II. DEVELOPMENT

A. INITIAL IMPETUS: ITCZ

B. INITIAL SURFACE VORTEX

1. 071800Z
2. Surface pressure less than 1007 mb.
3. Time storm reached hurricane intensity: 101800Z

C. 200 MB FLOW ABOVE SURFACE VORTEX

1. Initial: South to southeasterly as surface low progressed to west northwest under ridge aloft.
2. Upon reaching hurricane intensity: Southerly for next 60 hours gradually becoming variable as SARAH was temporarily downgraded to tropical storm intensity. Surface vortex was gradually caught up in northeast flow at 200 mb and recurved to the west while slowly intensifying.

III. FINAL DISPOSITION: SARAH crossed the date-line into FWC Guam's area of responsibility as a tropical storm with slow intensification continuing.

APPENDIX A

ABBREVIATIONS AND DEFINITIONS

1. Words and phrases that appear frequently in this report are abbreviated as follows:

APT	Automatic picture transmission (weather satellite)
CINCPAC	Commander in Chief, Pacific
CINCPACAF	Commander in Chief, Pacific Air Force
CINCPACFLT	Commander in Chief, Pacific Fleet
CIRC	Circulation
DEG	Degree(s)
DTG	Date-time group
FNWF	Fleet Numerical Weather Facility, Monterey California
FWC/JTWC	Fleet Weather Central/Joint Typhoon Warning Center, Guam, M. I.
54WRS	54th Weather Reconnaissance Squadron, Andersen AFB, Guam
ITCZ or ITC	Intertropical Convergence Zone
JHWC	Joint Hurricane Warning Center, Hawaii
KT(S)	Knots(s)
MAX	Maximum
MB(S)	Millibar(s)
MIN	Minimum
MI or N.M.	Nautical miles
NEDN	Naval Environmental Data Network
NESC	National Environmental Satellite Center, Suitland, Md.
POSIT(S)	Position(s)
SLP	Sea level pressure
T. D.	Tropical Depression
T. S.	Tropical Storm
VW1	Airborne Early Warning Squadron ONE, NAS, Agana, Guam

2. The following items define and clarify certain words and phrases that appear in the Eye Fix Summaries in Chapter V. Several definitions in this section have special meanings with regard to the machine prepared Eye Fix Summaries and may not necessarily have the same meaning as used elsewhere in the report.

a. FIX NO. - this number corresponds to the number of the fix plotted on the "Best Track Chart".

b. TIME - the date-time of the fix.

c. POSIT - the latitude and longitude of the fix.

d. UNIT - METHOD - ACCY:

(1) UNIT - the unit that made the fix if made by a reconnaissance squadron; 54-54WRS, VW-VW1.

(2) METHOD - the method used to make the fix; P - penetration, R - Radar (these two refer to fixes by reconnaissance squadrons), LND RDR - land radar, SHP RDR - ship radar, SLTLS - satellite cloud picture location, ACFT or ACFT RDR - aircraft other than reconnaissance squadrons.

(3) ACCY - center determination and estimated navigational accuracy of the fix (in nautical miles); P - positive, F - fair, L - poor.

EXAMPLE:

VW-R-P4: fix made by VW1 aircraft by radar, center determination positive, navigational accuracy given as 4 n.m.

e. FLT LVL - altitude of aircraft at time of fix in whole meters above mean sea level or given as a constant pressure surface; or, stage (STG) of development for a satellite location.

f. FLT LVL WND - maximum observed flight level wind speed in knots; or, diameter (DIA) in whole degrees of latitude for a satellite location.

g. OBS SFC WND - maximum observed surface wind speed in knots; or, number of bands (BNDS) for a satellite location.

h. OBS MIN SLP - minimum observed sea level pressure in whole millibars (reported on penetration fixes only).

i. MIN 700 MB HGT - minimum observed 700 mb level height in whole meters.

j. FLT LVL TT/TD - flight level temperature (TT) and dewpoint (TD) at fix location.

k. EYE FORM - description of cloud eye; CIRC - circular, ELIP - elliptical.

l. ORIENTATION - direction of orientation of an elliptical eye to an eight point compass.

m. EYE DIA - eye diameter or major/minor axes of an elliptical eye, in n.m.

n. THKNS WALL CLOUD - thickness of wall cloud in n.m. if observed. F.B. (feeder bands) or N.F.B. (no feeder bands) may be entered if wall cloud thickness not observed.

3. The following definitions are given to clarify usage in this report:

a. VORTICES:

(1) Cold vortex - a closed cyclonic circulation identified as having originated as a cold core system removed from the ITCZ or any easterly wave.

(2) Embedded vortex - a closed cyclonic circulation along an easterly wave and separated from the ITCZ.

(3) Junction vortex - a closed cyclonic circulation at the junction of an easterly wave and the ITCZ.

b. RECONNAISSANCE FLIGHTS:

(1) Synoptic track - a set reconnaissance pattern between specified coordinates scheduled to gather and report meteorological data.

(2) Investigative flight - weather reconnaissance of an area containing a suspected circulation.

(3) Fix mission - aircraft reconnaissance scheduled to fix the center position of and gather peripheral data about a known tropical cyclone.

c. Fix - the determination of the position of a tropical cyclone at a precise time, generally by reconnaissance aircraft penetration of the center or by airborne, land, or ship radar. In the case of a reconnaissance aircraft penetration the actual fix may be based on any of the following: visual observation of the cloud pattern and sea surface, radar, surface pressure, surface or flight level winds, constant pressure height, and temperature.

d. The term "tropical cyclone" has two definitions as used herein depending on usage:

(1) "Tropical cyclone" may be used to describe a suspected cyclonic circulation which appears to be capable of intensification.

(2) "Tropical cyclone" may be used in the general sense e.g., "Typhoon Carla was the most intense tropical cyclone of 1967", or "tropical cyclones most frequently develop during August and September".

e. TROPICAL DEPRESSION (T.D.) - as used by JTWC this is a numbered tropical cyclone in which the maximum sustained surface wind speed is 33 knots or less and whose winds are expected to increase to 34 knots or more within 48 hours.

f. TROPICAL STORM (T.S.) - a named tropical cyclone in which the maximum sustained surface wind speed is greater than 33 knots but less than 64 knots.

g. TYPHOON/HURRICANE - a named tropical cyclone in which the maximum sustained surface wind speeds are 64 knots or greater. West of 180 degrees longitude these are called typhoons, east of 180 degrees they are called hurricanes. All references to typhoons apply equally to hurricanes.

h. Recurvature - that point at which a tropical cyclone ceases movement to the west of north and commences moving east of north.
